Section 8.1

1. \[ 3x + 4 = 8 - x \]
   \[ 4x = 4 \]
   \[ x = 1 \]
   The solution set is \{1\}.

2. \( a. \quad 3x + 4y = 12 \)
   \( x\)-intercept: \( 3x + 4(0) = 12 \)
   \[ 3x = 12 \]
   \[ x = 4 \]
   \( y\)-intercept: \( 3(0) + 4y = 12 \)
   \[ 4y = 12 \]
   \[ y = 3 \]

   A parallel line would have slope \(-\frac{3}{4}\).

3. inconsistent

4. consistent

5. False

6. True

7. \[ \begin{cases} 2x - y = 5 \\ 5x + 2y = 8 \end{cases} \]

   Substituting the values of the variables:
   \[ \begin{cases} 2(2) - (-1) = 4 + 1 = 5 \\ 5(2) + 2(-1) = 10 - 2 = 8 \end{cases} \]

   Each equation is satisfied, so \( x = 2, y = -1 \), or \((2, -1)\), is a solution of the system.

8. \[ \begin{cases} 3x + 2y = 2 \\ x - 7y = -30 \end{cases} \]

   Substituting the values of the variables:
   \[ \begin{cases} 3(-2) + 2(4) = -6 + 8 = 2 \\ (-2) - 7(4) = -2 - 28 = -30 \end{cases} \]

   Each equation is satisfied, so \( x = -2, y = 4 \), or \((-2, 4)\), is a solution of the system.

9. \[ \begin{cases} 3x - 4y = 4 \\ \frac{1}{2} x - 3y = -\frac{1}{2} \end{cases} \]

   Substituting the values of the variables:
   \[ \begin{cases} 3(2) - 4\left(\frac{1}{2}\right) = 6 - 2 = 4 \\ \frac{1}{2}(2) - 3\left(\frac{1}{2}\right) = 1 - \frac{3}{2} = -\frac{1}{2} \end{cases} \]

   Each equation is satisfied, so \( x = 2, y = \frac{1}{2} \), or \(\left(2, \frac{1}{2}\right)\), is a solution of the system.

10. \[ \begin{cases} 2x + \frac{1}{2} y = 0 \\ 3x - 4y = -\frac{19}{2} \end{cases} \]

   Substituting the values of the variables, we obtain:
   \[ \begin{cases} 2\left(-\frac{1}{2}\right) + \frac{1}{2}(2) = -1 + 1 = 0 \\ 3\left(-\frac{1}{2}\right) - 4(2) = -\frac{3}{2} - 8 = -\frac{19}{2} \end{cases} \]

   Each equation is satisfied, so \( x = -\frac{1}{2}, y = 2 \), or \(\left(-\frac{1}{2}, 2\right)\), is a solution of the system.

11. \[ \begin{cases} \frac{1}{2} x - y = 3 \\ \frac{1}{2} y + x = 3 \end{cases} \]

   Substituting the values of the variables, we obtain:
   \[ \begin{cases} 2(2) - (-1) = 4 + 1 = 5 \\ 5(2) + 2(-1) = 10 - 2 = 8 \end{cases} \]

   Each equation is satisfied, so \( x = 2, y = -1 \), or \((2, -1)\), is a solution of the system.

12. \[ \begin{cases} x - y = 3 \\ \frac{1}{2} y + x = 3 \end{cases} \]

   Substituting the values of the variables:
   \[ \begin{cases} 4 - 1 = 3 \\ \frac{1}{2}(4) + 1 = 2 + 1 = 3 \end{cases} \]

   Each equation is satisfied, so \( x = 4, y = 1 \), or \((4, 1)\), is a solution of the system.
12. \[
\begin{align*}
\begin{cases}
x - y &= 3 \\
-3x + y &= 1
\end{cases}
\end{align*}
\]
Substituting the values of the variables:
\[
\begin{align*}
(2) - (-5) &= -2 + 5 = 3 \\
-3(-2) + (-5) &= 6 - 5 = 1
\end{align*}
\]
Each equation is satisfied, so \(x = -2, \ y = -5\), or \((-2, -5)\), is a solution of the system of equations.

13. \[
\begin{align*}
\begin{cases}
x - y + 3z &= 4 \\
2y - 3z &= -8
\end{cases}
\end{align*}
\]
Substituting the values of the variables:
\[
\begin{align*}
3(1) + 3(-1) + 2(2) &= 3 - 3 + 4 = 4 \\
1 - (-1) - 2 &= 1 + 1 - 2 = 0 \\
2(-1) - 3(2) &= -2 - 6 = -8
\end{align*}
\]
Each equation is satisfied, so \(x = 1, \ y = -1, \ z = 2\), or \((1, -1, 2)\), is a solution of the system of equations.

14. \[
\begin{align*}
\begin{cases}
x &- z = 7 \\
8x + 5y - z &= 0 \\
-x - y + 5z &= 6
\end{cases}
\end{align*}
\]
Substituting the values of the variables:
\[
\begin{align*}
4(2) - 1 &= 8 - 1 = 7 \\
8(2) + 5(-3) - 1 &= 16 - 15 - 1 = 0 \\
-2 - (-3) + 5(1) &= -2 + 3 + 5 = 6
\end{align*}
\]
Each equation is satisfied, so \(x = 2, \ y = -3, \ z = 1\), or \((2, -3, 1)\), is a solution of the system of equations.

15. \[
\begin{align*}
\begin{cases}
x - 3y + z &= 10 \\
5x - 2y - 3z &= 8
\end{cases}
\end{align*}
\]
Substituting the values of the variables:
\[
\begin{align*}
3(2) + 3(-2) + 2(2) &= 6 - 6 + 4 = 4 \\
2 - 3(-2) + 2 &= 2 + 6 + 2 = 10 \\
5(2) - 2(-2) - 3(2) &= 10 + 4 - 6 = 8
\end{align*}
\]
Each equation is satisfied, so \(x = 2, \ y = -2, \ z = 2\), or \((2, -2, 2)\), is a solution of the system of equations.

16. \[
\begin{align*}
\begin{cases}
4x &- 5z = 6 \\
5y - z &= -17 \\
x - 6y + 5z &= 24
\end{cases}
\end{align*}
\]
Substituting the values of the variables:
\[
\begin{align*}
4(4) - 5(2) &= 16 - 10 = 6 \\
5(-3) - (2) &= -15 - 2 = -17 \\
-(4) - 6(-3) + 5(2) &= -4 + 18 + 10 = 24
\end{align*}
\]
Each equation is satisfied, so \(x = 4, \ y = -3, \ z = 2\), or \((4, -3, 2)\), is a solution of the system of equations.

17. \[
\begin{align*}
\begin{cases}
x + y &= 8 \\
x - y &= 4
\end{cases}
\end{align*}
\]
Solve the first equation for \(y\), substitute into the second equation and solve:
\[
\begin{align*}
y &= 8 - x \\
x - y &= 4 \\
-x - y &= 4 \\
2x &= 12 \\
x &= 6
\end{align*}
\]
Since \(x = 6, \ y = 8 - 6 = 2\). The solution of the system is \(x = 6, \ y = 2\) or using ordered pairs \((6, 2)\).

18. \[
\begin{align*}
\begin{cases}
x + 2y &= 5 \\
x + \ y &= 3
\end{cases}
\end{align*}
\]
Solve the first equation for \(x\), substitute into the second equation and solve:
\[
\begin{align*}
x &= 5 - 2y \\
x + \ y &= 3 \\
(5 - 2y) + \ y &= 3 \\
5 - \ y &= 3 \\
2 &= \ y
\end{align*}
\]
Since \(y = 2, \ x = 5 - 2(2) = 1\). The solution of the system is \(x = 1, \ y = 2\) or using ordered pairs \((1, 2)\).
Chapter 8: Systems of Equations and Inequalities

19. \[
\begin{align*}
5x - y &= 13 \\
2x + 3y &= 12
\end{align*}
\]
Multiply each side of the first equation by 3 and add the equations to eliminate \(y\):
\[
\begin{align*}
15x - 3y &= 39 \\
2x + 3y &= 12
\end{align*}
\]
17\(x\) = 51
\(x\) = 3
Substitute and solve for \(y\):
5(3) – \(y\) = 13
15 – \(y\) = 13
\(-y\) = -2
\(y\) = 2
The solution of the system is \(x = 3\), \(y = 2\) or using ordered pairs (3, 2).

20. \[
\begin{align*}
x + 3y &= 5 \\
2x - 3y &= -8
\end{align*}
\]
Add the equations:
\[
\begin{align*}
x + 3y &= 5 \\
2x - 3y &= -8
\end{align*}
\]
3\(x\) = -3
\(x\) = -1
Substitute and solve for \(y\):
-1 + 3\(y\) = 5
3\(y\) = 6
\(y\) = 2
The solution of the system is \(x = -1\), \(y = 2\) or using ordered pairs (-1, 2).

21. \[
\begin{align*}
3x &= 24 \\
x + 2y &= 0
\end{align*}
\]
Solve the first equation for \(x\) and substitute into the second equation:
\[
\begin{align*}
x &= 8 \\
x + 2y &= 0
\end{align*}
\]
8 + 2\(y\) = 0
2\(y\) = -8
\(y\) = -4
The solution of the system is \(x = 8\), \(y = -4\) or using ordered pairs (8, -4)

22. \[
\begin{align*}
4x + 5y &= -3 \\
-2y &= -4
\end{align*}
\]
Solve the second equation for \(y\) and substitute into the first equation:
\[
\begin{align*}
4x + 5y &= -3 \\
y &= 2
\end{align*}
\]
4\(x\) + 5(2) = -3
4\(x\) + 10 = -3
4\(x\) = -13
\(x\) = -\(\frac{13}{4}\)
The solution of the system is \(x = -\frac{13}{4}\), \(y = 2\) or using ordered pairs \(-\frac{13}{4}, 2\).

23. \[
\begin{align*}
3x - 6y &= 2 \\
5x + 4y &= 1
\end{align*}
\]
Multiply each side of the first equation by 2 and each side of the second equation by 3, then add to eliminate \(y\):
\[
\begin{align*}
6x - 12y &= 4 \\
15x + 12y &= 3
\end{align*}
\]
21\(x\) = 7
\(x\) = \(\frac{1}{3}\)
Substitute and solve for \(y\):
3(1/3) – 6\(y\) = 2
1 – 6\(y\) = 2
-6\(y\) = 1
\(y\) = -\(\frac{1}{6}\)
The solution of the system is \(x = \frac{1}{3}\), \(y = -\frac{1}{6}\) or using ordered pairs \(\left(\frac{1}{3}, -\frac{1}{6}\right)\).
Section 8.1: Systems of Linear Equations: Substitution and Elimination

24. \[
\begin{align*}
2x + 4y &= \frac{2}{3} \\
3x - 5y &= -10 \\
\end{align*}
\]
Multiply each side of the first equation by 5 and each side of the second equation by 4, then add to eliminate \(y\):

\[
\begin{align*}
10x + 20y &= \frac{10}{3} \\
12x - 20y &= -40 \\
\end{align*}
\]

\[
22x = \frac{110}{3}
\]

\[
x = \frac{-5}{3}
\]

Substitute and solve for \(y\):

\[
3\left(-\frac{5}{3}\right) - 5y = -10
\]

\[
-5 - 5y = -10
\]

\[
-5y = -5
\]

\[
y = 1
\]

The solution of the system is \(x = \frac{-5}{3}, y = 1\) or using ordered pairs \((-\frac{5}{3}, 1)\).

25. \[
\begin{align*}
2x + y &= 1 \\
4x + 2y &= 3 \\
\end{align*}
\]
Solve the first equation for \(y\), substitute into the second equation and solve:

\[
\begin{align*}
y &= 1 - 2x \\
4x + 2y &= 3 \\
\end{align*}
\]

\[
4x + 2(1 - 2x) = 3
\]

\[
4x + 2 - 4x = 3
\]

\[
0 = 1
\]

This equation is false, so the system is inconsistent.

26. \[
\begin{align*}
x - y &= 5 \\
-3x + 3y &= 2 \\
\end{align*}
\]
Solve the first equation for \(x\), substitute into the second equation and solve:

\[
\begin{align*}
x &= y + 5 \\
-3x + 3y &= 2 \\
\end{align*}
\]

\[
-3(y + 5) + 3y = 2
\]

\[
-3y - 15 + 3y = 2
\]

\[
0 = 17
\]

This equation is false, so the system is inconsistent.

27. \[
\begin{align*}
2x - y &= 0 \\
3x + 2y &= 7 \\
\end{align*}
\]
Solve the first equation for \(y\), substitute into the second equation and solve:

\[
\begin{align*}
y &= 2x \\
3x + 2(2x) &= 7 \\
3x + 4x &= 7 \\
7x &= 7 \\
x &= 1
\end{align*}
\]

Since \(x = 1, y = 2(1) = 2\)

The solution of the system is \(x = 1, y = 2\) or using ordered pairs \((1, 2)\).

28. \[
\begin{align*}
3x + 3y &= -1 \\
4x + y &= \frac{8}{3} \\
\end{align*}
\]
Solve the second equation for \(y\), substitute into the first equation and solve:

\[
\begin{align*}
y &= \frac{8}{3} - 4x \\
3x + 3\left(\frac{8}{3} - 4x\right) &= -1 \\
3x + 8 - 12x &= -1 \\
-9x &= -9 \\
x &= 1
\end{align*}
\]

Since \(x = 1, y = \frac{8}{3} - 4(1) = \frac{8}{3} - 4 = -\frac{4}{3}\).

The solution of the system is \(x = 1, y = -\frac{4}{3}\) or using ordered pairs \((1, -\frac{4}{3})\).

29. \[
\begin{align*}
x + 2y &= 4 \\
2x + 4y &= 8 \\
\end{align*}
\]
Solve the first equation for \(x\), substitute into the second equation and solve:

\[
\begin{align*}
x &= 4 - 2y \\
2x + 4y &= 8 \\
2(4 - 2y) + 4y &= 8 \\
8 - 4y + 4y &= 8 \\
0 &= 0
\end{align*}
\]

These equations are dependent. The solution of the system is either \(x = 4 - 2y\), where \(y\) is any real
number or \( y = \frac{4-x}{2} \), where \( x \) is any real number.

Using ordered pairs, we write the solution as \( \{(x, y) \mid x = 4-2y, \ y \text{ is any real number} \} \) or as \( \{(x, y) \mid y = \frac{4-x}{2}, \ x \text{ is any real number} \} \).

30. \[
\begin{align*}
3x - y &= 7 \\
9x - 3y &= 21
\end{align*}
\]
Solve the first equation for \( y \), substitute into the second equation and solve:
\[
\begin{align*}
y &= 3x - 7 \\
9x - 3y &= 21 \\
9x - 3(3x - 7) &= 21 \\
9x - 9x + 21 &= 21 \\
0 &= 0
\end{align*}
\]
These equations are dependent. The solution of the system is either \( y = 3x - 7 \), where \( x \) is any real number is \( x = \frac{y+7}{3} \), where \( y \) is any real number.

Using ordered pairs, we write the solution as \( \{(x, y) \mid y = 3x - 7, \ x \text{ is any real number} \} \) or as \( \{(x, y) \mid x = \frac{y+7}{3}, \ y \text{ is any real number} \} \).

31. \[
\begin{align*}
2x - 3y &= -1 \\
10x + y &= 11
\end{align*}
\]
Multiply each side of the first equation by \(-5\), and add the equations to eliminate \( x \):
\[
\begin{align*}
-10x + 15y &= 5 \\
10x + y &= 11 \\
16y &= 16 \\
y &= 1
\end{align*}
\]
Substitute and solve for \( x \):
\[
\begin{align*}
2x - 3(1) &= -1 \\
2x - 3 &= -1 \\
2x &= 2 \\
x &= 1
\end{align*}
\]
The solution of the system is \( x = 1, \ y = 1 \) or using ordered pairs \((1, 1)\).

32. \[
\begin{align*}
3x - 2y &= 0 \\
5x + 10y &= 4
\end{align*}
\]
Multiply each side of the first equation by \(5\), and add the equations to eliminate \( y \):
\[
\begin{align*}
15x - 10y &= 0 \\
5x + 10y &= 4 \\
20x &= 4 \\
x &= \frac{1}{5}
\end{align*}
\]
Substitute and solve for \( y \):
\[
\begin{align*}
5\left(\frac{1}{5}\right) + 10y &= 4 \\
1 + 10y &= 4 \\
10y &= 3 \\
y &= \frac{3}{10}
\end{align*}
\]
The solution of the system is \( x = \frac{1}{5}, \ y = \frac{3}{10} \) or using ordered pairs \( \left(\frac{1}{5}, \frac{3}{10}\right) \).

33. \[
\begin{align*}
2x + 3y &= 6 \\
x - y &= \frac{1}{2}
\end{align*}
\]
Solve the second equation for \( x \), substitute into the first equation and solve:
\[
\begin{align*}
2x + 3y &= 6 \\
x &= y + \frac{1}{2} \\
2\left(y + \frac{1}{2}\right) + 3y &= 6 \\
2y + 1 + 3y &= 6 \\
5y &= 5 \\
y &= 1
\end{align*}
\]
Since \( y = 1, \ x = 1 + \frac{1}{2} = \frac{3}{2} \). The solution of the system is \( x = \frac{3}{2}, \ y = 1 \) or using ordered pairs \( \left(\frac{3}{2}, 1\right) \).
Section 8.1: Systems of Linear Equations: Substitution and Elimination

34. \[
\begin{align*}
\frac{1}{2}x + y &= -2 \\
x - 2y &= 8
\end{align*}
\]
Solve the second equation for \(x\), substitute into the first equation and solve:

\[
\begin{align*}
\frac{1}{2}x + y &= -2 \\
x &= 2y + 8 \\
\frac{1}{2}(2y + 8) + y &= -2 \\
y + 4 + y &= -2 \\
2y &= -6 \\
y &= -3
\end{align*}
\]
Since \(y = -3\), \(x = 2(-3) + 8 = -6 + 8 = 2\). The solution of the system is \(x = 2, \ y = -3\) or using ordered pairs \((2, -3)\).

35. \[
\begin{align*}
\frac{1}{2}x + \frac{1}{3}y &= 3 \\
\frac{1}{4}x - \frac{2}{3}y &= -1
\end{align*}
\]
Multiply each side of the first equation by \(-6\) and each side of the second equation by \(12\), then add to eliminate \(x\):

\[
\begin{align*}
-3x - 2y &= -18 \\
3x - 8y &= -12 \\
-10y &= -30 \\
y &= 3
\end{align*}
\]
Substitute and solve for \(x\):

\[
\begin{align*}
\frac{1}{2}x + \frac{1}{3}(3) &= 3 \\
\frac{1}{2}x + 1 &= 3 \\
\frac{1}{2}x &= 2 \\
x &= 4
\end{align*}
\]
The solution of the system is \(x = 4, \ y = 3\) or using ordered pairs \((4, 3)\).

36. \[
\begin{align*}
\frac{1}{3}x - \frac{1}{2}y &= -5 \\
\frac{3}{4}x + \frac{1}{3}y &= 11
\end{align*}
\]
Multiply each side of the first equation by \(-5\) and each side of the second equation by \(24\), then add to eliminate \(x\):

\[
\begin{align*}
-18x + 81y &= 270 \\
18x + 8y &= 264 \\
89y &= 534 \\
y &= 6
\end{align*}
\]
Substitute and solve for \(x\):

\[
\begin{align*}
\frac{3}{4}x + \frac{1}{3}(6) &= 11 \\
\frac{3}{4}x + 2 &= 11 \\
\frac{3}{4}x &= 9 \\
x &= 12
\end{align*}
\]
The solution of the system is \(x = 12, \ y = 6\) or using ordered pairs \((12, 6)\).

37. \[
\begin{align*}
3x - 5y &= 3 \\
15x + 5y &= 21
\end{align*}
\]
Add the equations to eliminate \(y\):

\[
\begin{align*}
3x - 5y &= 3 \\
15x + 5y &= 21 \\
18x &= 24 \\
x &= \frac{4}{3}
\end{align*}
\]
Substitute and solve for \(y\):

\[
\begin{align*}
3\left(\frac{4}{3}\right) - 5y &= 3 \\
4 - 5y &= 3 \\
-5y &= -1 \\
y &= \frac{1}{5}
\end{align*}
\]
The solution of the system is \(x = \frac{4}{3}, \ y = \frac{1}{5}\) or using ordered pairs \(\left(\frac{4}{3}, \frac{1}{5}\right)\).
Chapter 8: Systems of Equations and Inequalities

38. \[
\begin{align*}
2x - y &= -1 \\
x + \frac{1}{2}y &= \frac{3}{2}
\end{align*}
\]
Multiply each side of the second equation by 2, and add the equations to eliminate \(y\):
\[
\begin{align*}
2x - y &= -1 \\
2x + y &= 3 \\
4x &= 2 \\
x &= \frac{1}{2}
\end{align*}
\]
Substitute and solve for \(y\):
\[
2\left(\frac{1}{2}\right) - y = -1
\]
\[
1 - y = -1
\]
\[
y = 2
\]
The solution of the system is \(x = \frac{1}{2}, y = 2\) or using ordered pairs \(\left(\frac{1}{2}, 2\right)\).

39. \[
\begin{align*}
\frac{1}{x} + \frac{1}{y} &= 8 \\
\frac{3}{x} - \frac{5}{y} &= 0
\end{align*}
\]
Rewrite letting \(u = \frac{1}{x}, v = \frac{1}{y}\):
\[
\begin{align*}
u + v &= 8 \\
3u - 5v &= 0
\end{align*}
\]
Solve the first equation for \(u\), substitute into the second equation and solve:
\[
\begin{align*}
u &= 8 - v \\
3u - 5v &= 0
\end{align*}
\]
\[
3(8 - v) - 5v = 0
\]
\[
24 - 3v - 5v = 0
\]
\[
-8v = -24
\]
\[
v = 3
\]
Since \(v = 3\), \(u = 8 - 3 = 5\). Thus, \(x = \frac{1}{u} = \frac{1}{5}\), \(y = \frac{1}{v} = \frac{1}{3}\). The solution of the system is \(x = \frac{1}{5}, y = \frac{1}{3}\) or using ordered pairs \(\left(\frac{1}{5}, \frac{1}{3}\right)\).

40. \[
\begin{align*}
\frac{4}{x} - \frac{3}{y} &= 0 \\
\frac{6}{x} + \frac{3}{2y} &= 2
\end{align*}
\]
Rewrite letting \(u = \frac{1}{x}, v = \frac{1}{y}\):
\[
\begin{align*}
4u - 3v &= 0 \\
6u + \frac{3}{2}v &= 2
\end{align*}
\]
Multiply each side of the second equation by 2, and add the equations to eliminate \(v\):
\[
\begin{align*}
4u - 3v &= 0 \\
12u + 3v &= 4
\end{align*}
\]
\[
u = \frac{4}{16} = \frac{1}{4}
\]
Substitute and solve for \(v\):
\[
4\left(\frac{1}{4}\right) - 3v = 0
\]
\[
1 - 3v = 0
\]
\[
-3v = -1
\]
\[
v = \frac{1}{3}
\]
Thus, \(x = \frac{1}{u} = 4, y = \frac{1}{v} = 3\). The solution of the system is \(x = 4, y = 3\) or using ordered pairs \((4, 3)\).

41. \[
\begin{align*}
x - y &= 6 \\
2x - 3z &= 16 \\
2y + z &= 4
\end{align*}
\]
Multiply each side of the first equation by \(-2\) and add to the second equation to eliminate \(x\):
\[
\begin{align*}
-2x + 2y &= -12 \\
2x - 3z &= 16
\end{align*}
\]
\[
2y - 3z = 4
\]
Multiply each side of the result by \(-1\) and add to the original third equation to eliminate \(y\):
\[
\begin{align*}
-2y + 3z &= -4 \\
2y + z &= 4
\end{align*}
\]
\[
4z = 0
\]
\[
z = 0
\]
Substituting and solving for the other variables:
Section 8.1: Systems of Linear Equations: Substitution and Elimination

2y + 0 = 4  
2y = 4  
y = 2

2x - 3(0) = 16  
2x = 16  
x = 8

The solution is x = 8, y = 2, z = 0 or using ordered triplets (8, 2, 0).

42. \begin{align*}
2x + y &= -4 \\
-2y + 4z &= 0 \\
3x - 2z &= -11 
\end{align*}

Multiply each side of the first equation by 2 and add to the second equation to eliminate y:

4x + 2y &= -8 \\
-2y + 4z &= 0 \\
4x + 4z &= -8

Multiply each side of the result by \( \frac{1}{2} \) and add to the original third equation to eliminate z:

2x + 2z = -4  
3x - 2z = -11  
5x = -15  
x = -3

Substituting and solving for the other variables:

\begin{align*}
2(-3) + y &= -4 \\
-6 + y &= -4 \\
y &= 2 \\
-2z &= -2 \\
z &= 1 
\end{align*}

The solution is x = -3, y = 2, z = 1 or using ordered triplets (-3, 2, 1).

43. \begin{align*}
x - 2y + 3z &= 7 \\
2x + y + 3z &= 4 \\
-3x + 2y - 2z &= -10 
\end{align*}

Multiply each side of the first equation by -2 and add to the second equation to eliminate x; and multiply each side of the first equation by 3 and add to the third equation to eliminate x:

-2x + 4y - 6z = -14  
2x + y + 3z = 4  
5y - 5z = -10

Substituting and solving for the other variables:

\begin{align*}
2(-3) + y &= -4 \\
-6 + y &= -4 \\
y &= 2 \\
-2z &= -2 \\
z &= 1 
\end{align*}

The solution is x = 3, y = 2, z = 1 or using ordered triplets (3, 2, 1).

44. \begin{align*}
4y - 4z &= -8 \\
-4y + 7z &= 11 \\
3z &= 3 \\

\end{align*}

Substituting and solving for the other variables:

\begin{align*}
y - 1 &= -2 \\
x - 2(-1) + 3(1) &= 7 \\
y &= -1 \\
x &= 2 
\end{align*}

The solution is x = 2, y = -1, z = 1 or using ordered triplets (2, -1, 1).

43. \begin{align*}
x - 2y + 3z &= 7 \\
2x + y + 3z &= 4 \\
-3x + 2y - 2z &= -10 
\end{align*}

Multiply each side of the first equation by -2 and add to the second equation to eliminate y; and multiply each side of the first equation by 4 and add to the third equation to eliminate y:

-4x - 2y + 6z = 0  
-2x + 2y + z = -7  
-6x + 7z = -7

Multiply each side of the first result by 11 and multiply each side of the second result by 6 to eliminate x:

-66x + 77z = -77  
66x - 90z = 42  
-13z = -35  
z = 35  
13

Substituting and solving for the other variables:

\begin{align*}
-6x + 7\left(\frac{35}{13}\right) &= -7 \\
-6x + \frac{245}{13} &= -7 \\
-6x &= \frac{-336}{13} \\
x &= \frac{56}{13} 
\end{align*}
Chapter 8: Systems of Equations and Inequalities

2 \left( \frac{56}{13} \right) + y - 3 \left( \frac{35}{13} \right) = 0

\frac{112}{13} + y - \frac{105}{13} = 0

y = -\frac{7}{13}

The solution is \( x = \frac{56}{13}, y = -\frac{7}{13}, z = \frac{35}{13} \) or using ordered triplets \( \left( \frac{56}{13}, -\frac{7}{13}, \frac{35}{13} \right) \).

Add the first and second equations to eliminate \( z \):

\begin{align*}
2x + 3y + z &= 2 \\
3x + 2y &= 0
\end{align*}

Multiply each side of the result by \(-1\) and add to the original third equation to eliminate \( y \):

\begin{align*}
-3x - 2y &= -3 \\
3x + 2y &= 0 \\
0 &= -3
\end{align*}

This equation is false, so the system is inconsistent.

Add the first and second equations to eliminate \( z \); then add the second and third equations to eliminate \( z \):

\begin{align*}
2x - 3y - z &= 0 \\
-x + 2y + z &= 5 \\
3x - 4y - z &= 1
\end{align*}

Multiply each side of the first result by \(-2\) and add to the second result to eliminate \( y \):

\begin{align*}
-2x + 2y &= -10 \\
2x - 2y &= 6 \\
0 &= -2
\end{align*}

This equation is false, so the system is inconsistent.

Add the first and second equations to eliminate \( x \); multiply the first equation by \(-3\) and add to the third equation to eliminate \( x \):

\begin{align*}
x - y - z &= 1 \\
x - 2y - 3z &= -4 \\
3x - 2y - 7z &= 0
\end{align*}

\begin{align*}
x - y - z &= 1 \\
x - 2y - 3z &= -4 \\
y - 4z &= -3
\end{align*}

The system is dependent. If \( z \) is any real number, then \( y = 4z - 3 \).

Solving for \( x \) in terms of \( z \) in the first equation:

\begin{align*}
x &= (4z - 3) - z \\
x &= 4z - 3
\end{align*}

The solution is \( (x, y, z) \mid x = 5z - 2, y = 4z - 3, z \text{ is any real number} \).

\end{align*}
\]
The system is dependent. If \(y\) is any real number, then \(x = \frac{4}{7}y + \frac{2}{7}\).

Solving for \(z\) in terms of \(x\) in the first equation:
\[z = 2x - 3y\]
\[= 2 \left( \frac{4y + 2}{7} \right) - 3y\]
\[= \frac{8y + 4 - 21y}{7}\]
\[= -\frac{13y + 4}{7}\]
The solution is \(\{(x, y, z) | x = \frac{4}{7}y + \frac{2}{7}, z = -\frac{13}{7}y + \frac{4}{7}, y\text{ is any real number}\}\).

\[
\begin{align*}
-6x + 4y - 4z &= -12 \\
2x - 3y + 4z &= 0

Add the first result to the second result to eliminate \(y\):
\[
\begin{align*}
4x - y &= -7 \\

55. Let \( l \) be the length of the rectangle and \( w \) be the width of the rectangle. Then:
\[
2lw = 22 - 90
\]
Solve by substitution:
\[
2(2w) = 90
4w = 90
w = 15 \text{ feet}
\]
\[
l = 2(15) = 30 \text{ feet}
\]
The floor is 15 feet by 30 feet.

56. Let \( l \) be the length of the rectangle and \( w \) be the width of the rectangle. Then:
\[
50l + w = 2\,200
\]
Solve by substitution:
\[
2(50) = 2\,200
725 \text{ meters}
\]
\[
l = 725 + 50 = 775 \text{ meters}
\]
The dimensions of the field are 775 meters by 725 meters.

57. Let \( x \) be the number of commercial launches and \( y \) be the number of noncommercial launches. Then:
\[
x + y = 55 \quad \text{and} \quad y = 2x + 1
\]
Solve by substitution:
\[
x + (2x + 1) = 55
3x = 54
x = 18
\]
\[
y = 2(18) + 1
y = 36 + 1
y = 37
\]
In 2005 there were 18 commercial launches and 37 noncommercial launches.

58. Let \( x \) be the number of adult tickets sold and \( y \) be the number of senior tickets sold. Then:
\[
\begin{align*}
x + y &= 325 \\
9x + 7y &= 2495
\end{align*}
\]
Solve the first equation for \( y \):
\[
y = 325 - x
\]
Solve by substitution:
\[
9x + 7(325 - x) = 2495
2x = 220
x = 110
\]
\[
y = 325 - 110 = 215
\]
There were 110 adult tickets sold and 215 senior citizen tickets sold.

59. Let \( x \) be the number of pounds of cashews. Let \( y \) be the number of pounds in the mixture. Then:
\[
5x + 3y = \text{amount of mixture}
\]
Solve by substitution:
\[
x = 18 \quad y = 37
\]
So, 22.5 pounds of cashews should be used in the mixture.

60. Let \( x \) be the amount invested in AA bonds. Let \( y \) be the amount invested in the Bank Certificate.
\[
a. \quad x + y = 150,000 \quad \text{represents the total investment.}
\]
\[
0.10x + 0.05y = 12,000 \quad \text{represents the earnings on the investment.}
\]
Solve by substitution:
\[
0.10(150,000) + 0.05y = 12,000
15,000 - 0.10y + 0.05y = 12,000
-0.05y = -3000
y = 60,000
x = 150,000 - 60,000 = 90,000
Thus, $90,000 should be invested in AA Bonds and $60,000 in a Bank Certificate.
\]
\[
b. \quad x + y = 150,000 \quad \text{represents the total investment.}
\]
\[
0.10x + 0.05y = 14,000 \quad \text{represents the earnings on the investment.}
\]
Solve by substitution:
\[
0.10(150,000) + 0.05y = 14,000
15,000 - 0.10y + 0.05y = 14,000
-0.05y = -1000
y = 20,000
x = 150,000 - 20,000 = 130,000
Thus, $130,000 should be invested in AA Bonds and $20,000 in a Bank Certificate.
61. Let \( x \) = the plane’s airspeed and \( y \) = the wind speed.

<td>4</td>
</tr>
</tbody>
</table>

\[
\begin{align*}
(x + y)(3) &= 600 \\
(x - y)(4) &= 600
\end{align*}
\]

Multiply each side of the first equation by \( \frac{1}{3} \),

and add the result to eliminate \( y \)

\[
x + y = 200 \\
x - y = 150
\]

\[
\begin{align*}
2x &= 350 \\
x &= 175
\end{align*}
\]

175 + \( y \) = 200

\( y \) = 25

The airspeed of the plane is 175 mph, and the

wind speed is 25 mph.

62. Let \( x \) = the wind speed and \( y \) = the distance.

<table>
<thead>
<tr>
<th>Rate</th>

<tr>
<td>With Wind</td>
<td>( 150 + x )</td>
<td>2</td>
</tr>
<tr>

<td>3</td>
</tr>
</tbody>
</table>

\[
\begin{align*}
(150 + x)(2) &= y \\
(150 - x)(3) &= y
\end{align*}
\]

Solve by substitution:

\[
\begin{align*}
(150 + x)(2) &= (150 - x)(3) \\
300 + 2x &= 450 - 3x
\end{align*}
\]

\[
\begin{align*}
5x &= 150 \\
x &= 30
\end{align*}
\]

Thus, the wind speed is 30 mph.

63. Let \( x \) = the number of $25-design.
Let \( y \) = the number of $45-design.

Then \( x + y \) = the total number of sets of dishes.

25\( x \) + 45\( y \) = the cost of the dishes.

Setting up the equations and solving by substitution:

\[
\begin{align*}
x + y &= 200 \\
25x + 45y &= 7400
\end{align*}
\]

Solve the first equation for \( y \), the solve by substitution:

\( y = 200 - x \)

25\( x \) + 45(200 - \( x \)) = 7400

25\( x \) + 9000 - 45\( x \) = 7400

-20\( x \) = -1600

\( x = 80 \)

\( y = 200 - 80 = 120 \)

Thus, 80 sets of the $25 dishes and 120 sets of the $45 dishes should be ordered.

64. Let \( x \) = the cost of a hot dog.
Let \( y \) = the cost of a soft drink.

Setting up the equations and solving by substitution:

\[
\begin{align*}
10x + 5y &= 35.00 \\
7x + 4y &= 25.25
\end{align*}
\]

10\( x \) + 5\( y \) = 35.00

2\( x \) + \( y \) = 7

\( y = 7 - 2x \)

7\( x \) + 4(7 - 2\( x \)) = 25.25

7\( x \) + 28 - 8\( x \) = 25.25

-\( x = -2.75 \)

\( x = 2.75 \)

\( y = 7 - 2(2.75) = 1.50 \)

A single hot dog costs $2.75 and a single soft drink costs $1.50.

65. Let \( x \) = the cost per package of bacon.
Let \( y \) = the cost of a carton of eggs.

Set up a system of equations for the problem:

\[
\begin{align*}
3x + 2y &= 13.45 \\
2x + 3y &= 11.45
\end{align*}
\]

Multiply each side of the first equation by 3 and

each side of the second equation by –2 and solve

by elimination:

\[
\begin{align*}
9x + 6y &= 40.35 \\
-4x - 6y &= -22.90
\end{align*}
\]

\[
\begin{align*}
5x &= 17.45 \\
x &= 3.49
\end{align*}
\]

Substitute and solve for \( y \):

3(3.49) + 2\( y \) = 13.45

10.47 + 2\( y \) = 13.45

\( 2\( y \) = 2.98 \\
\( y = 1.49 \)

A package of bacon costs $3.49 and a carton of

eggs cost $1.49. The refund for 2 packages of

bacon and 2 cartons of eggs will be

2($3.49) + 2($1.49) = $9.96.

66. Let \( x \) = Pamela’s speed in still water. Let \( y \) = the speed of the current.

</tr>
<tr>
<td>Upstream</td>
<td>( x - y )</td>

</tbody>
</table>

Set up a system of equations for the problem:

\[
\begin{align*}
3(x + y) &= 15 \\
5(x - y) &= 15
\end{align*}
\]

Multiply each side of the first equation by \( \frac{1}{3} \), multiply each side of the second equation by \( \frac{1}{5} \), and add the result to eliminate \( y \):

\[
\begin{align*}
5 - 3x + 5y &= 0 \\
\ &= 28
\end{align*}
\]

\[
\begin{align*}
4x &= -28 \\
\ &= -4
\end{align*}
\]

So \( x = 4 \) miles per hour and the speed of the current is 1 mile per hour.

67. Let \( x \) = the # of mg of compound 1. Let \( y \) = the # of mg of compound 2.

Setting up the equations and solving by substitution:

\[
\begin{align*}
0.2x + 0.4y &= 40 \quad \text{vitamin C} \\
0.3x + 0.2y &= 30 \quad \text{vitamin D}
\end{align*}
\]

Multiplying each equation by 10 yields

\[
\begin{align*}
2x + 4y &= 400 \\
6x + 4y &= 600
\end{align*}
\]

Subtracting the bottom equation from the top equation yields

\[
\begin{align*}
2x + 4y - (6x + 4y) &= 400 - 600 \\
-4x &= -200 \\
x &= 50
\end{align*}
\]

\[
\begin{align*}
2(50) + 4y &= 400 \\
100 + 4y &= 400 \\
4y &= 300 \\
y &= \frac{300}{4} = 75
\end{align*}
\]

So 50 mg of compound 1 should be mixed with 75 mg of compound 2.

68. Let \( x \) = the # of units of powder 1. Let \( y \) = the # of units of powder 2.

Setting up the equations and solving by substitution:

\[
\begin{align*}
0.2x + 0.4y &= 12 \quad \text{vitamin B}_{12} \\
0.3x + 0.2y &= 12 \quad \text{vitamin E}
\end{align*}
\]

Multiplying each equation by 10 yields

\[
\begin{align*}
2x + 4y &= 120 \\
6x + 4y &= 240
\end{align*}
\]

Subtracting the bottom equation from the top equation yields

\[
\begin{align*}
2x + 4y - (6x + 4y) &= 120 - 240 \\
-4x &= -120 \\
x &= 30
\end{align*}
\]

\[
\begin{align*}
2(30) + 4y &= 120 \\
60 + 4y &= 120 \\
4y &= 60 \\
y &= \frac{60}{4} = 15
\end{align*}
\]

So 30 units of powder 1 should be mixed with 15 units of powder 2.

69. \( y = ax^2 + bx + c \)

At \((-1, 4)\) the equation becomes:

\[
4 = a(-1)^2 + b(-1) + c
\]

\[
4 = a - b + c
\]

At \((2, 3)\) the equation becomes:

\[
3 = a(2)^2 + b(2) + c
\]

\[
3 = 4a + 2b + c
\]

At \((0, 1)\) the equation becomes:

\[
1 = a(0)^2 + b(0) + c
\]

\[
1 = c
\]

The system of equations is:

\[
\begin{align*}
a - b + c &= 4 \\
4a + 2b + c &= 3 \\
c &= 1
\end{align*}
\]

Substitute \( c = 1 \) into the first and second equations and simplify:

\[
\begin{align*}
a - b + 1 &= 4 \\
4a + 2b + 1 &= 3 \\
a - b &= 3 \\
4a + 2b &= 2
\end{align*}
\]

\[
\begin{align*}
a &= b + 3
\end{align*}
\]

Solve the first result for \( a \), substitute into the second result and solve:
Chapter 8: Systems of Equations and Inequalities

4(b + 3) + 2b = 2
4b + 12 + 2b = 2
6b = −10
b = −\frac{5}{3}

\[a = −\frac{5}{3} + 3 = \frac{4}{3}\]

The solution is \(a = \frac{4}{3}, \quad b = −\frac{5}{3}, \quad c = 1\). The equation is \(y = \frac{4}{3}x^2 − \frac{5}{3}x + 1\).

71. \[\begin{align*}
0.06Y − 5000r &= 240 \\
0.06Y + 6000r &= 900
\end{align*}\]
Multiply the first equation by \(-1\), the add the result to the second equation to eliminate \(Y\): \(-0.06Y + 5000r = −240\)
\[
\begin{align*}
0.06Y + 6000r &= 900 \\
11000r &= 660 \\
r &= 0.06
\end{align*}
\]
Substitute this result into the first equation to find \(Y\):
\[
\begin{align*}
0.06Y − 5000(0.06) &= 240 \\
0.06Y − 300 &= 240 \\
0.06Y &= 540 \\
Y &= 9000
\end{align*}
\]
The equilibrium level of income and interest rates is $9000 million and 6%.

72. \[\begin{align*}
0.05Y − 1000r &= 10 \\
0.05Y + 800r &= 100
\end{align*}\]
Multiply the first equation by \(-1\), the add the result to the second equation to eliminate \(Y\):
\[
\begin{align*}
−0.05Y + 1000r &= −10 \\
0.05Y + 800r &= 100 \\
1800r &= 90 \\
r &= 0.05
\end{align*}
\]
Substitute this result into the first equation to find \(Y\):
\[
\begin{align*}
0.05Y − 1000(0.05) &= 10 \\
0.05Y − 50 &= 10 \\
0.05Y &= 60 \\
Y &= 1200
\end{align*}
\]
The equilibrium level of income and interest rates is $1200 million and 5%.

73. \[\begin{align*}
5I_2 − 3I_1 &= 0 \\
10− 5I_2 − 7I_3 &= 0
\end{align*}\]
Substitute the expression for \(I_2\) into the second and third equations and simplify:
\[
\begin{align*}
5 − 3I_1 − 5(I_1 + I_3) &= 0 \\
−8I_1 − 5I_3 &= −5 \\
10 − 5(I_1 + I_3) − 7I_3 &= 0 \\
−5I_1 − 12I_3 &= −10
\end{align*}
\]
Multiply both sides of the first result by 5 and multiply both sides of the second result by \(-8\) to eliminate \(I_1\):
Section 8.1: Systems of Linear Equations: Substitution and Elimination

Substituting and solving for the other variables:

\[
\begin{align*}
-40I_1 - 25I_3 &= -25 \\
40I_1 + 96I_3 &= 80 \\
71I_3 &= 55 \\
I_3 &= \frac{55}{71}
\end{align*}
\]

Substituting and solving for the other variables:

\[
\begin{align*}
-8I_1 - 5\left(\frac{55}{71}\right) &= -5 \\
-8I_1 - \frac{275}{71} &= -5 \\
-8I_1 &= \frac{80}{71} \\
I_1 &= \frac{10}{71}
\end{align*}
\]

\[
I_2 = \left(\frac{10}{71}\right) + \frac{55}{71} = \frac{65}{71}
\]

The solution is \( I_1 = \frac{10}{71}, I_2 = \frac{65}{71}, I_3 = \frac{55}{71} \).

74. \[
\begin{align*}
I_3 &= I_1 + I_2 \\
8 &= 4I_3 + 6I_2 \\
8I_1 &= 4 + 6I_2
\end{align*}
\]

Substitute the expression for \( I_3 \) into the second equation and simplify:

\[
\begin{align*}
8 &= 4(I_1 + I_2) + 6I_2 \\
8 &= 4I_1 + 10I_2 \\
8I_1 - 6I_2 &= 4
\end{align*}
\]

Multiply both sides of the first result by \(-2\) and add to the second result to eliminate \( I_1 \):

\[
\begin{align*}
-8I_1 - 20I_2 &= -16 \\
8I_1 - 6I_2 &= 4 \\
-26I_2 &= -12 \\
I_2 &= \frac{12}{26} = \frac{6}{13}
\end{align*}
\]

Substituting and solving for the other variables:

\[
\begin{align*}
4I_1 + 10\left(\frac{6}{13}\right) &= 8 \\
4I_1 + \frac{60}{13} &= 8 \\
4I_1 &= \frac{44}{13} \\
I_1 &= \frac{11}{13}
\end{align*}
\]

\[
I_3 = I_1 + I_2 = \frac{11}{13} + \frac{6}{13} = \frac{17}{13}
\]

The solution is \( I_1 = \frac{11}{13}, I_2 = \frac{6}{13}, I_3 = \frac{17}{13} \).

75. Let \( x \) = the number of orchestra seats.
Let \( y \) = the number of main seats.
Let \( z \) = the number of balcony seats.

Since the total number of seats is 500, \( x + y + z = 500 \).
Since the total revenue is $17,100 if all seats are sold, \( 50x + 35y + 25z = 17,100 \).
If only half of the orchestra seats are sold, the revenue is $14,600.

So, \( 50\left(\frac{1}{2}x\right) + 35y + 25z = 14,600 \).

Thus, we have the following system:

\[
\begin{align*}
x + y + z &= 500 \\
50x + 35y + 25z &= 17,100 \\
25x + 35y + 25z &= 14,600
\end{align*}
\]

Multiply each side of the first equation by \(-25\) and add to the second equation to eliminate \( z \); multiply each side of the third equation by \(-1\) and add to the second equation to eliminate \( z \):

\[
\begin{align*}
-25x - 25y - 25z &= -12,500 \\
50x + 35y + 25z &= 17,100 \\
25x + 10y &= 4600 \\
50x + 35y + 25z &= 17,100 \\
-25x - 35y - 25z &= -14,600 \\
25x &= 2500 \\
x &= 100
\end{align*}
\]

Substituting and solving for the other variables:

\[
\begin{align*}
25(100) + 10y &= 4600 \\
100 + 210 + z &= 500 \\
2500 + 10y &= 4600 \\
310 + z &= 500 \\
10y &= 2100 \\
z &= 190 \\
y &= 210
\end{align*}
\]

There are 100 orchestra seats, 210 main seats, and 190 balcony seats.
Chapter 8: Systems of Equations and Inequalities

76. Let $x$ = the number of adult tickets.
Let $y$ = the number of child tickets.
Let $z$ = the number of senior citizen tickets.
Since the total number of tickets is 405,
\[ x + y + z = 405. \]
Since the total revenue is $2320,
\[ 8x + 4.50y + 6z = 2320. \]
Twice as many children's tickets as adult tickets are sold. So, \[ 2y = x. \]
Thus, we have the following system:
\[
\begin{align*}
405 & = x + y + z, \\
8x + 4.50y + 6z & = 2320, \\
y & = 2x.
\end{align*}
\]
Substitute for $y$ in the first two equations and simplify:
\[
\begin{align*}
x + (2x) + z & = 405, \\
3x + z & = 405, \\
8x + 4.50(2x) + 6z & = 2320, \\
17x + 6z & = 2320.
\end{align*}
\]
Multiply the first result by –6 and add to the second result to eliminate $z$:
\[
\begin{align*}
-18x - 6z & = -2430, \\
17x + 6z & = 2320,
\end{align*}
\]
\[ -x = -110 \]
\[ x = 110 \]
\[ y = 2x \]
\[ = 2(110) \]
\[ = 220 \]
\[ 3x + z = 405 \]
\[ = 3(110) + z = 405 \]
\[ = 330 + z = 405 \]
\[ z = 75 \]
There were 110 adults, 220 children, and 75 senior citizens that bought tickets.

77. Let $x$ = the number of servings of chicken.
Let $y$ = the number of servings of corn.
Let $z$ = the number of servings of 2% milk.
Protein equation: \[ 30x + 3y + 9z = 66 \]
Carbohydrate equation: \[ 35x + 16y + 13z = 94.5 \]
Calcium equation: \[ 200x + 10y + 300z = 910 \]
Multiply each side of the first equation by –16 and multiply each side of the second equation by 3 and add them to eliminate $y$; multiply each side of the second equation by –5 and multiply each side of the third equation by 8 and add to eliminate $y$:
\[
\begin{align*}
-480x - 48y - 144z & = -1056, \\
105x + 48y + 39z & = 283.5, \\
-375x & = -105z = -772.5, \\
-175x - 80y - 65z & = -472.5, \\
1600x + 80y + 2400z & = 7280, \\
1425x & + 2335z = 6807.5.
\end{align*}
\]
Multiply each side of the first result by 19 and multiply each side of the second result by 5 to eliminate $x$:
\[
\begin{align*}
-7125x - 1995z & = -14,677.5, \\
7125x + 11,675z & = 34,037.5, \\
9680z & = 19,360, \\
z & = 2.
\end{align*}
\]
Substituting and solving for the other variables:
\[
\begin{align*}
-375x - 105(2) & = -772.5, \\
-375x - 210 & = -772.5, \\
-375x & = -562.5, \\
x & = 1.5, \\
30(1.5) + 3y + 9(2) & = 66, \\
45 + 3y + 18 & = 66, \\
3y & = 3, \\
y & = 1.
\end{align*}
\]
The dietitian should serve 1.5 servings of chicken, 1 serving of corn, and 2 servings of 2% milk.

78. Let $x$ = the amount in Treasury bills.
Let $y$ = the amount in Treasury bonds.
Let $z$ = the amount in corporate bonds.
Since the total investment is $20,000,
\[ x + y + z = 20,000 \]
Since the total income is to be $1390,
\[ 0.05x + 0.07y + 0.10z = 1390 \]
The investment in Treasury bills is to be $3000 more than the investment in corporate bonds. So, 
\[ x = 3000 + z \]
Substitute for $x$ in the first two equations and simplify:
\[
\begin{align*}
(3000 + z) + y + z & = 20,000, \\
y + 2z & = 17,000, \\
5(3000 + z) + 7y + 10z & = 139,000, \\
7y + 15z & = 124,000.
\end{align*}
\]
Multiply each side of the first result by \(-7\) and add to the second result to eliminate \(y\):

\[
-7y - 14z = -119,000 \\
7y + 15z = 124,000
\]

\[
z = 5,000 \\
x = 3000 + z = 3000 + 5000 = 8000 \\
y + 2z = 17,000 \\
y + 2(5000) = 17,000 \\
y + 10,000 = 17,000
\]

\[
y = 7000
\]

Kelly should invest $8000 in Treasury bills, $7000 in Treasury bonds, and $5000 in corporate bonds.

79. Let \(x\) = the price of 1 hamburger.
Let \(y\) = the price of 1 order of fries.
Let \(z\) = the price of 1 drink.

We can construct the system
\[
\begin{align*}
8x + 6y + 6z &= 26.10 \\
10x + 6y + 8z &= 31.60
\end{align*}
\]

A system involving only 2 equations that contain 3 or more unknowns cannot be solved uniquely.

Multiply the first equation by \(-\frac{1}{2}\) and the second equation by \(\frac{1}{2}\), then add to eliminate \(y\):

\[
\begin{align*}
-4x - 3y - 3z &= -13.05 \\
5x + 3y + 4z &= 15.80
\end{align*}
\]

\[
x + z = 2.75 \\
x = 2.75 - z
\]

Substitute and solve for \(y\) in terms of \(z\):

\[
5(2.75 - z) + 3y + 4z = 15.80 \\
13.75 + 3y - z = 15.80 \\
3y = z + 2.05 \\
y = \frac{1}{3}z + \frac{41}{60}
\]

Solutions of the system are: \(x = 2.75 - z\), \(y = \frac{1}{3}z + \frac{41}{60}\).

Since we are given that \(0.60 \leq z \leq 0.90\), we choose values of \(z\) that give two-decimal-place values of \(x\) and \(y\) with \(1.75 \leq x \leq 2.25\) and \(0.75 \leq y \leq 1.00\).

The possible values of \(x\), \(y\), and \(z\) are shown in the table.

80. Let \(x\) = the price of 1 hamburger.
Let \(y\) = the price of 1 order of fries.
Let \(z\) = the price of 1 drink

We can construct the system
\[
\begin{align*}
8x + 6y + 6z &= 26.10 \\
10x + 6y + 8z &= 31.60 \\
3x + 2y + 4z &= 10.95
\end{align*}
\]

Subtract the second equation from the first equation to eliminate \(y\):

\[
\begin{align*}
8x + 6y + 6z &= 26.10 \\
10x + 6y + 8z &= 31.60 \\
-2x - 2z &= -5.5
\end{align*}
\]

Multiply the third equation by \(-3\) and add it to the second equation to eliminate \(y\):

\[
\begin{align*}
10x + 6y + 8z &= 31.60 \\
9x - 6y - 12z &= -32.85 \\
x - 4z &= -1.25
\end{align*}
\]

Multiply the second result by 2 and add it to the first result to eliminate \(x\):

\[
\begin{align*}
-2x - 2z &= -5.5 \\
2x - 8z &= -2.5 \\
-10z &= -8
\end{align*}
\]

\[
z = 0.8
\]

Multiply the second result by 2 and add it to the first result to eliminate \(x\):

\[
\begin{align*}
-2x - 2z &= -5.5 \\
2x - 8z &= -2.5 \\
-10z &= -8
\end{align*}
\]

\[
z = 0.8
\]

Substitute for \(z\) to find the other variables:

\[
\begin{align*}
x - 4(0.8) &= -1.25 \\
x - 3.2 &= -1.25 \\
x &= 1.95
\end{align*}
\]

\[
\begin{align*}
3(1.95) + 2y + 4(0.8) &= 10.95 \\
5.85 + 2y + 3.2 &= 10.95 \\
2y &= 1.9 \\
y &= 0.95
\end{align*}
\]

Therefore, one hamburger costs $1.95, one order of fries costs $0.95, and one drink costs $0.80.
Chapter 8: Systems of Equations and Inequalities

81. Let \( x \) = Beth’s time working alone.
Let \( y \) = Bill’s time working alone.
Let \( z \) = Edie’s time working alone.

We can use the following tables to organize our work:

<table>
<thead>
<tr>
<th></th>
<th>Beth</th>
<th>Bill</th>
<th>Edie</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hours to do job</td>
<td>( x )</td>
<td>( y )</td>
<td>( z )</td>
</tr>
<tr>
<td>Part of job done in 1 hour</td>
<td>( \frac{1}{x} )</td>
<td>( \frac{1}{y} )</td>
<td>( \frac{1}{z} )</td>
</tr>
</tbody>
</table>

In 10 hours they complete 1 entire job, so
\[
10 \left( \frac{1}{x} + \frac{1}{y} + \frac{1}{z} \right) = 1
\]
\[
\frac{1}{x} + \frac{1}{y} + \frac{1}{z} = \frac{1}{10}
\]

<table>
<thead>
<tr>
<th></th>
<th>Bill</th>
<th>Edie</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hours to do job</td>
<td>( y )</td>
<td>( z )</td>
</tr>
<tr>
<td>Part of job done in 1 hour</td>
<td>( \frac{1}{y} )</td>
<td>( \frac{1}{z} )</td>
</tr>
</tbody>
</table>

In 15 hours they complete 1 entire job, so
\[
15 \left( \frac{1}{y} + \frac{1}{z} \right) = 1
\]
\[
\frac{1}{y} + \frac{1}{z} = \frac{1}{15}
\]

<table>
<thead>
<tr>
<th></th>
<th>Beth</th>
<th>Bill</th>
<th>Edie</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hours to do job</td>
<td>( x )</td>
<td>( y )</td>
<td>( z )</td>
</tr>
<tr>
<td>Part of job done in 1 hour</td>
<td>( \frac{1}{x} )</td>
<td>( \frac{1}{y} )</td>
<td>( \frac{1}{z} )</td>
</tr>
</tbody>
</table>

With all 3 working for 4 hours and Beth and Bill working for an additional 8 hours, they complete 1 entire job, so
\[
4 \left( \frac{1}{x} + \frac{1}{y} + \frac{1}{z} \right) + 8 \left( \frac{1}{x} + \frac{1}{y} \right) = 1
\]
\[
\frac{12}{x} + \frac{12}{y} + \frac{4}{z} = 1
\]

We have the system
\[
\begin{align*}
\frac{1}{x} + \frac{1}{y} + \frac{1}{z} &= \frac{1}{10} \\
\frac{1}{y} + \frac{1}{z} &= \frac{1}{15} \\
\frac{12}{x} + \frac{12}{y} + \frac{4}{z} &= 1
\end{align*}
\]

Subtract the second equation from the first equation:
\[
\begin{align*}
\frac{1}{x} + \frac{1}{y} + \frac{1}{z} &= \frac{1}{10} \\
\frac{1}{y} + \frac{1}{z} &= \frac{1}{15} \\
\frac{12}{x} + \frac{12}{y} + \frac{4}{z} &= 1
\end{align*}
\]

Substitute \( x = 30 \) into the third equation:
\[
\begin{align*}
\frac{12}{30} + \frac{12}{y} + \frac{4}{z} &= 1 \\
\frac{4}{y} + \frac{1}{z} &= \frac{1}{5}
\end{align*}
\]

Now consider the system consisting of the last result and the second original equation. Multiply the second original equation by \(-12\) and add it to the last result to eliminate \( y \):
\[
\begin{align*}
\frac{12}{y} + \frac{4}{z} &= \frac{3}{5} \\
-\frac{8}{z} &= -\frac{3}{15} \\
z &= 40
\end{align*}
\]

Plugging \( z = 40 \) to find \( y \):
\[
\begin{align*}
\frac{12}{y} + \frac{4}{z} &= \frac{3}{5} \\
\frac{12}{y} &= \frac{1}{2} \\
y &= 24
\end{align*}
\]

Working alone, it would take Beth 30 hours, Bill 24 hours, and Edie 40 hours to complete the job.

\]
(R_4 = \frac{1}{2}r_3)

(R_4 = -\frac{1}{35}r_4)

Write the matrix as the corresponding system:
\[
\begin{align*}

\]
Substitute and solve:
\[
\begin{align*}
x + 2(0) + z &= 1 \\
y &= 0 \\
z &= 1 - x
\end{align*}
\]
The solution is \( y = 0, z = 1 - x, x \) is any real number or \( \{(x, y, z) \mid y = 0, z = 1 - x, x \text{ is any real number}\} \).

66. \[
\begin{align*}
x + 2y - z &= 3 \\
2x - y + 2z &= 6 \\
x - 3y + 3z &= 4
\end{align*}
\]
Write the augmented matrix:
\[
\begin{bmatrix}
1 & 2 & -1 & 3 \\
2 & -1 & 2 & 6 \\
1 & -3 & 3 & 4
\end{bmatrix}

(R_2 = -2r_1 + r_2)
\rightarrow

\]
There is no solution. The system is inconsistent.

67. \[
\begin{align*}
x - y + z &= 5 \\

\]
Write the augmented matrix:
\[

(R_3 = \frac{1}{5}r_2)
\rightarrow
\begin{bmatrix}
1 & 0 & 0 & 2 \\
0 & 1 & 1 & -3

\]
or, equivalently,
\[
\begin{cases}

Thus, the solution is \( x = 2, y = z - 3, z \) is any real number or \( \{(x, y, z) \mid x = 2, y = z - 3, z \text{ is any real number}\} \).

The matrix in the last step represents the system
\[
\begin{align*}
x &= 1 + \frac{4}{3} z \\
y &= 2 - \frac{5}{3} z \\

0 & 5 & 1 & | & 3 \\
0 & 0 & 0 & | & 0 \\
0 & 2 & 4 & | & 5 \\
\end{bmatrix}
\]
The matrix in the last step represents the system
\[
\begin{align*}
x - 8z &= -7 \\
y - 7z &= -7 \\
z &= \frac{19}{18}
\end{align*}
\]
Substitute and solve:
\[
\begin{align*}
y - 7\left(\frac{19}{18}\right) &= 7 \\
x - 8\left(\frac{19}{18}\right) &= -7 \\
\end{align*}
\]
\[
\begin{align*}
x &= \frac{13}{9} \\
y &= \frac{7}{18} \\
z &= \frac{19}{18}
\end{align*}
\]
Thus, the solution is \(x = \frac{13}{9}, \ y = \frac{7}{18}, \ z = \frac{19}{18}\) or \(\left\{\frac{13}{9}, \frac{7}{18}, \frac{19}{18}\right\}\).

70. \[
\begin{align*}
2x - y - 4z &= 0 \\

\]
Write the augmented matrix:
\[
\begin{bmatrix}
1 & -3 & 1 & | & 1 \\
2 & -1 & -4 & | & 0 \\
1 & -3 & 2 & | & 1 \\
1 & -2 & 0 & | & 5
\end{bmatrix}
\]
Section 8.2: Systems of Linear Equations: Matrices

71. \[
\begin{align*}
4x + y + z - w &= 4 \\
x - y + 2z + 3w &= 3
\end{align*}
\]
Write the augmented matrix:
\[
\begin{bmatrix}
4 & 1 & 1 & -1 & 4 \\
1 & -1 & 2 & 3 & 3 \\
\end{bmatrix}
\]
\[
\begin{bmatrix}
1 & -1 & 2 & 3 & 3 \\
4 & 1 & 1 & -1 & 4 \\
\end{bmatrix}
\]
\[
\begin{bmatrix}
1 & -1 & 2 & 3 & 3 \\
0 & 5 & -7 & -13 & -8 \\
\end{bmatrix}
\]
The matrix in the last step represents the system:
\[
\begin{align*}
x - y + 2z + 3w &= 3 \\
5y - 7z - 13w &= -8
\end{align*}
\]
The second equation yields:
\[
5y - 7z - 13w = -8
\]
\[
y = \frac{7}{5}z + \frac{13}{5}w - \frac{8}{5}
\]
The first equation yields:
\[
x - y + 2z + 3w = 3
\]
\[
x = 3 + y - 2z - 3w
\]
Substituting for \(y\):
\[
x = 3 + \left( -\frac{8}{5} + \frac{7}{5}z + \frac{13}{5}w \right) - 2z - 3w
\]
\[
x = -\frac{3}{5}z - \frac{2}{5}w + \frac{7}{5}
\]
Thus, the solution is:
\[
x = -\frac{3}{5}z - \frac{2}{5}w + \frac{7}{5},
\]
\[
y = \frac{7}{5}z + \frac{13}{5}w - \frac{8}{5},
\]
z and \(w\) are any real numbers.

72. \[
\begin{align*}
2x - y + z - w &= 5 \\
z + w &= 4
\end{align*}
\]
Write the augmented matrix:
\[
\begin{bmatrix}
-4 & 1 & 0 & 0 & 5 \\
2 & -1 & 1 & -1 & 5 \\
0 & 0 & 1 & 1 & 4
\end{bmatrix}
\]
\[
\begin{bmatrix}
1 & -\frac{1}{2} & 0 & 0 & -\frac{5}{4} \\
0 & 0 & 1 & 1 & 4 \\
1 & -\frac{1}{2} & 0 & 0 & -\frac{5}{4} \\
0 & 0 & 1 & 1 & 4 \\
1 & -\frac{1}{2} & 0 & 0 & -\frac{5}{4} \\
0 & 0 & 1 & 1 & 4 \\
\end{bmatrix}
\]
The matrix in the last step represents the system:
\[
\begin{align*}
x + w &= -3 \\
y + 4w &= -7 \\
z + w &= 4
\end{align*}
\]
The solution is:
\[
\begin{align*}
(x, w, y, z) &= (x = -3 - w, w = 4, y = -7 - 4w, z + 4 - w) \\
&\text{or, equivalently, } (x = -3 - w, w = 4, y = -7 - 4w, z = 4 - w)
\end{align*}
\]
w is any real number or \(\{(w, x, y, z) | x = -3 - w, w = 4, y = -7 - 4w, z = 4 - w, x, y, w, z\} \text{ is any real number}\)
Chapter 8: Systems of Equations and Inequalities

73. Each of the points must satisfy the equation
\[ y = ax^2 + bx + c \ . \]

\((1, 2): \ 2 = a + b + c\)
\((-2, -7): \ -7 = 4a - 2b + c\)
\((2, -3): \ -3 = 4a + 2b + c\)

Set up a matrix and solve:

\[
\begin{bmatrix}
1 & 1 & 1 & 2 \\
4 & -2 & 1 & -7 \\
4 & 2 & 1 & -3 \\
\end{bmatrix}
\]

\[
\begin{bmatrix}
1 & 1 & 1 & 2 \\
0 & -6 & -3 & -15 \\
0 & -2 & -3 & -11 \\
\end{bmatrix}
\]

\[
\begin{bmatrix}
1 & 1 & 1 & 2 \\
0 & 1 & \frac{1}{2} & \frac{5}{2} \\
0 & -2 & -3 & -11 \\
\end{bmatrix}
\]

\[
\begin{bmatrix}
0 & 0 & 1 & \frac{1}{2} \\
0 & 0 & 1 & 3 \\
\end{bmatrix}
\]

\[
\begin{bmatrix}
1 & 1 & 0 & -2 \\
0 & 1 & 0 & 1 \\
0 & 0 & 1 & 3 \\
\end{bmatrix}
\]

The solution is \( a = 1, b = -4, c = 2 \); so the equation is \( y = x^2 - 4x + 2 \).

74. Each of the points must satisfy the equation
\[ y = ax^2 + bx + c \ . \]

\((1, 1): \ 1 = a + b + c\)
\((-2, 14): \ 14 = 4a - 2b + c\)

Set up a matrix and solve:

\[
\begin{bmatrix}
1 & 1 & 1 & -1 \\
9 & 3 & 1 & -1 \\
4 & -2 & 1 & 14 \\
\end{bmatrix}
\]

\[
\begin{bmatrix}
1 & 1 & 1 & -1 \\
0 & -6 & -8 & 8 \\
0 & -6 & -3 & 18 \\
\end{bmatrix}
\]

The solution is \( a = -2, b = 1, c = 3 \); so the equation is \( y = -2x^2 + x + 3 \).

75. Each of the points must satisfy the equation
\[ f(x) = ax^3 + bx^2 + cx + d \ . \]

\[ f(-3) = -12: \ -27a + 9b - 3c + d = -112 \]
\[ f(-1) = -2: \ -a + b - c + d = -2 \]
\[ f(1) = 4: \ a + b + c + d = 4 \]
\[ f(2) = 13: \ 8a + 4b + 2c + d = 13 \]

Set up a matrix and solve:

\[
\begin{bmatrix}
27 & 9 & -3 & 1 & -112 \\
1 & -1 & -1 & 1 & -2 \\
1 & 1 & 1 & 1 & 4 \\
8 & 4 & 2 & 1 & 13 \\
\end{bmatrix}
\]

The solution is \( a = 1, b = 0, c = 0, d = 1 \); so the equation is \( y = x^3 + x + 1 \).

Section 8.2: Systems of Linear Equations: Matrices

Each of the points must satisfy the equation $f(x) = ax^3 + bx^2 + cx + d$.

$$f(-2) = -10: \quad -8a + 4b - 2c + d = -10$$
$$f(-1) = 3: \quad -a + b - c + d = 3$$
$$f(1) = 5: \quad a + b + c + d = 5$$
$$f(3) = 15: \quad 27a + 9b + 3c + d = 15$$

Set up a matrix and solve:

\[
\begin{bmatrix}
3 & 1 & 1 & 5 \\
1 & 1 & 1 & -1 \\
1 & 1 & 1 & -8 \\
-8 & 3 & 1 & 27 \\
\end{bmatrix}
\rightarrow
\begin{bmatrix}
1 & 1 & 1 & 5 \\
-1 & -1 & -1 & 3 \\
-8 & 4 & -2 & 1 \\
27 & 9 & 3 & 1 \\
\end{bmatrix}
\]

(Interchange $r_3$ and $r_1$)

\[
\begin{bmatrix}
1 & 1 & 1 & 5 \\
0 & 2 & 0 & 2 \\
0 & 12 & 6 & 9 \\
0 & -18 & -24 & -26 \\
\end{bmatrix}
\rightarrow
\begin{bmatrix}
1 & 1 & 1 & 5 \\
0 & 2 & 0 & 2 \\
0 & 12 & 6 & 9 \\
0 & -18 & -24 & -26 \\
\end{bmatrix}
\]

\[
\begin{bmatrix}
1 & 0 & 1 & 4 \\
0 & 12 & 6 & 9 \\
0 & -18 & -24 & -26 \\
\end{bmatrix}
\]

The solution is $a = 3, b = -4, c = 0, d = 5$; so the equation is $f(x) = 3x^3 - 4x^2 + 5$.

Let $z$ = the number of servings of acorn squash.

Protein equation: $30x + 15y + 3z = 78$

Carbohydrate equation: $20x + 2y + 25z = 59$

Vitamin A equation: $2x + 20y + 32z = 75$

Set up a matrix and solve:

\[
\begin{bmatrix}
30 & 15 & 3 & 78 \\
20 & 2 & 25 & 59 \\
2 & 20 & 32 & 75 \\
\end{bmatrix}
\rightarrow
\begin{bmatrix}
2 & 20 & 32 & 75 \\
20 & 2 & 25 & 59 \\
30 & 15 & 3 & 78 \\
\end{bmatrix}
\]

(Interchange $r_3$ and $r_1$)

\[
\begin{bmatrix}
30 & 15 & 3 & 78 \\
2 & 20 & 32 & 75 \\
20 & 2 & 25 & 59 \\
30 & 15 & 3 & 78 \\
\end{bmatrix}

0 & -198 & -295 & -691 \\
0 & -285 & -477 & -1047 \\
\end{bmatrix}
\]

The solution is $x = 1, y = -2, z = 0, d = 6$; so the equation is $f(x) = x^3 - 2x^2 + 6$.

77. Let $x = \frac{1}{2}r_1 + r_2$.

\Rightarrow \begin{bmatrix} 2 & 0 & 2.5 \\ 0 & -4 & -0.5 \end{bmatrix} \quad (R_1 = \eta_1 + r_2)
\]

The matrix in the last step represents the system
\[
\begin{align*}
2x + 2.5z &= 60 \\
-4y - 0.5z &= -60
\end{align*}
\]

Thus, the solution is \(x = 30 - 1.25z\),
\(y = 15 - 0.125z\), \(z\) is any real number.

\end{bmatrix}
\]

\[
\begin{bmatrix}
0 & 4 & -3 \\

Since \(D = 0\), Cramer's Rule does not apply.
Chapter 8: Systems of Equations and Inequalities

\[ D_y = \begin{vmatrix} 1 & 0 & -3 \\ 3 & 0 & 3 \\ 1 & 0 & 6 \end{vmatrix} = 0 \quad \text{[By Theorem (12)]} \]

\[ D_z = \begin{vmatrix} 1 & 4 & 0 \\ 3 & -1 & 0 \\ 1 & 1 & 0 \end{vmatrix} = 0 \quad \text{[By Theorem (12)]} \]

Find the solutions by Cramer's Rule:

\[ x = \frac{D_x}{D} = \frac{0}{-81} = 0 \quad y = \frac{D_y}{D} = \frac{0}{-81} = 0 \]

\[ z = \frac{D_z}{D} = \frac{0}{-81} = 0 \]

The solution is (0, 0, 0).

43. Solve for \( x \):

\[
\begin{vmatrix} x & x \\ 4 & 3 \end{vmatrix} = 5
\]

\[ 3x - 4x = 5 \]

\[ -x = 5 \]

\[ x = -5 \]

44. Solve for \( x \):

\[
\begin{vmatrix} x & 1 \\ 3 & x \end{vmatrix} = -2
\]

\[ x^2 - 3 = -2 \]

\[ x^2 - 1 = 0 \]

\[ (x-1)(x+1) = 0 \]

\[ x-1 = 0 \quad \text{or} \quad x+1 = 0 \]

\[ x = 1 \quad \text{or} \quad x = -1 \]

45. Solve for \( x \):

\[
\begin{vmatrix} 1 & 1 \\ 4 & 3 & 2 \end{vmatrix} = 2
\]

\[ -1 & 2 & 5 \]

\[ x \]

\[ \begin{vmatrix} 3 & 2 & 4 & 1 \\ 2 & 5 & -1 & 4 \\ 2 & 5 & 1 & -1 \end{vmatrix} = 2 \]

\[ x(15-4) - (20+2) + (8+3) = 2 \]

\[ 11x - 22 + 11 = 2 \]

\[ 11x = 13 \]

\[ x = \frac{13}{11} \]

46. Solve for \( x \):

\[
\begin{vmatrix} 3 & 2 & 4 \\ 0 & 1 & -2 \end{vmatrix} = 0
\]

\[ x \]

\[ \begin{vmatrix} 3 & 2 & 4 \\ 1 & 5 & 0 \end{vmatrix} = 0 \]

\[ 0 & 1 & -2 \]

\[ x \]

\[ \begin{vmatrix} 3 & 5 & 0 \\ -2 & -2 & 1 \end{vmatrix} = 0 \]

\[ 0 & 1 \]

\[ 3(-2x-5) - 2(-2) + 4(1) = 0 \]

\[ -6x - 15 + 4 + 4 = 0 \]

\[ -6x - 7 = 0 \]

\[ -6x = 7 \]

\[ x = -\frac{7}{6} \]
47. Solve for \( x \):
\[
\begin{vmatrix}

\end{vmatrix} = 7 \\
\begin{vmatrix}
1 & 0 & -2 \\
1 & 0 & 1 \\
6 & 1 & 6
\end{vmatrix} = 7 \\
x(-2x) - 2(-2) + 3(1-6x) = 7 \\
-2x^2 + 4 + 3 - 18x = 7 \\
-2x^2 - 18x = 0 \\
-2x(x+9) = 0 \\
x = 0 \text{ or } x = -9
\]

48. Solve for \( x \):
\[
\begin{vmatrix}

0 & 1 & 2
\end{vmatrix} = -4x \\
\begin{vmatrix}
3 & 2 & -1 \\
0 & 2 & 1 \\
1 & 1 & 0
\end{vmatrix} = -4x \\
x(2x-3)-1(2)+2(1) = -4x \\
2x^2 - 3x + 2 = -4x \\
2x^2 + x = 0 \\
x(x+1) = 0 \\
x = 0 \text{ or } x = -\frac{1}{2}
\]

49. Let
\[
\begin{vmatrix}

By Theorem (11), the value of a determinant changes sign if any two rows are interchanged.
Thus,

\]

52. Let
\[

\begin{vmatrix}

\end{vmatrix} = -1(\text{1}) \\
\begin{vmatrix}
x & y & z \\
1 & 2 & 3 \\
x & y & z
\end{vmatrix} = 4
\]

53. Let
\[
\begin{vmatrix}
x & y & z \\
1 & 2 & 3 \\

\end{vmatrix} = 4
\]
[Theorem (11)]
\[
\begin{vmatrix}

Chapter 8: Systems of Equations and Inequalities

56. Let \[
\begin{vmatrix}
  x & y & z \\
  u & v & w \\
  1 & 2 & 3
\end{vmatrix}
= 4
\]

57. Expanding the determinant:

\[
\begin{vmatrix}
  x & y & 1 \\
  x_1 & y_1 & 1 \\
  x_2 & y_2 & 1
\end{vmatrix} = 0
\]

This is the 2-point form of the equation for a line.
58. Any point \((x, y)\) on the line containing \((x_2, y_2)\) and \((x_3, y_3)\) satisfies:

\[
\begin{vmatrix}
    x & y & 1 \\
    x_2 & y_2 & 1 \\
    x_3 & y_3 & 1 \\
\end{vmatrix} = 0
\]

If the point \((x_1, y_1)\) is on the line containing \((x_2, y_2)\) and \((x_3, y_3)\) [the points are collinear], then

\[
\begin{vmatrix}
    x_1 & y_1 & 1 \\
    x_2 & y_2 & 1 \\
    x_3 & y_3 & 1 \\
\end{vmatrix} = 0 .
\]

Conversely, if \(x_2 \neq x_3\) then \((x_1, y_1)\) is on the line containing \((x_2, y_2)\) and \((x_3, y_3)\), and the points are collinear.

59. Let \(A = (x_1, y_1)\), \(B = (x_2, y_2)\), and \(C = (x_3, y_3)\) represent the vertices of a triangle. For simplicity, we position our triangle in the first quadrant. See figure. Let \(A\) be the point closest to the \(y\)-axis, \(C\) be the point farthest from the \(y\)-axis, and \(B\) be the point “between” points \(A\) and \(C\).

Let \(D = (x_1, 0)\), \(E = (x_2, 0)\), and \(F = (x_3, 0)\).

We find the area of triangle \(ABC\) by subtracting the areas of trapezoids \(ADEB\) and \(BEFC\) from the area of trapezoid \(ADFC\). Note: \(AD = y_1\), \(BE = y_2\), \(CF = y_3\), \(DF = x_3 - x_1\), \(DE = x_2 - x_1\), and \(EF = x_3 - x_2\). Thus, the areas of the three trapezoids are as follows:

\[
K_{ADFC} = \frac{1}{2} \left( x_3 - x_1 \right) (y_1 + y_3) 
\]

\[
K_{AEB} = \frac{1}{2} \left( x_2 - x_1 \right) (y_1 + y_2), \text{ and}
\]

\[
K_{BEFC} = \frac{1}{2} \left( x_3 - x_2 \right) (y_2 + y_3).
\]

The area of our triangle \(ABC\) is

\[
K_{ABC} = K_{ADFC} - K_{AEB} - K_{BEFC}
\]

Expanding \(D\), we obtain

\[
D = \frac{1}{2} \begin{vmatrix}
    x_1 & x_2 & x_3 \\
    y_1 & y_2 & y_3 \\
    1 & 1 & 1 \\
\end{vmatrix}
\]

\[
= \frac{1}{2} \left( x_1 y_2 - x_2 y_1 + x_2 y_3 - x_3 y_2 + x_3 y_1 - x_1 y_3 \right) 
\]

which is the same as the area of triangle \(ABC\).

If the vertices of the triangle are positioned differently than shown in the figure, the signs may be reversed. Thus, the absolute value of \(D\) will give the area of the triangle.

If the vertices of a triangle are \((2, 3)\), \((5, 2)\), and \((6, 5)\), then:

\[
D = \frac{1}{2} \begin{vmatrix}
    2 & 5 & 6 \\
    3 & 2 & 5 \\
    1 & 1 & 1 \\
\end{vmatrix}
\]

\[
= \frac{1}{2} \left[ 2(-5) - 5(3 - 5) + (6 - 2) \right] 
\]

\[
= \frac{1}{2} \left[ -10 + 10 + 6 \right] 
\]

\[
= 5
\]

The area of the triangle is \(|S| = 5\) square units.
60. Expanding the determinant:
\[
\begin{vmatrix}
 x^2 & x & 1 \\
 y^2 & y & 1 \\
 z^2 & z & 1 \\
\end{vmatrix}
\]
\[
= x^2 \begin{vmatrix} y & 1 \\ z & 1 \end{vmatrix} - x \begin{vmatrix} y^2 & 1 \\ z^2 & 1 \end{vmatrix} + 1 \begin{vmatrix} y^2 & y \\ z^2 & z \end{vmatrix}
\]
\[
= x^2(y-z) - x(y^2 - z^2) + 1(y^2z - z^2y)
\]
\[
= x^2(y-z) - x(y-z)(y+z) + yz(y-z)
\]
\[
= (y-z)\left[x^2 - xy - xz + yz \right]
\]
\[
= (y-z)(x(y-x) - z(x-y))
\]

61. If \(a=0\), then \(b \neq 0\) and \(c \neq 0\) since \(ad-bc \neq 0\), and the system is \(\begin{array}{l}
by = s \\
\end{array}\)

The solution of the system is \(y = \frac{s}{b}\).

\[
x = \frac{t-dy}{c} = \frac{t-d\left(\frac{s}{b}\right)}{c} = \frac{tb - sd}{bc}.
\]

Using Cramer’s Rule, we get \(D = \begin{vmatrix} 0 & b \\ c & d \end{vmatrix} = -bc\),

\[
D_x = \begin{vmatrix} s & b \\ c & t \end{vmatrix} = sd - tb,
\]

\[
D_y = \begin{vmatrix} 0 & s \\ c & t \end{vmatrix} = sc - sc = 0,
\]

\[
x = \frac{D_x}{D} = \frac{ds - tb}{-bc} = \frac{td - sd}{bc} \quad \text{and}
\]

\[
y = \frac{D_y}{D} = \frac{-sc}{-bc} = \frac{s}{b},
\]

which is the solution. Note that these solutions agree if \(d = 0\).

If \(b = 0\), then \(a \neq 0\) and \(d \neq 0\) since \(ad-bc \neq 0\), and the system is \(\begin{array}{l}
ax = s \\
\end{array}\)

The solution of the system is \(x = \frac{s}{a}\),

\[
y = \frac{t-cx}{d} = \frac{at-cs}{d}.
\]

Using Cramer’s Rule, we get \(D = \begin{vmatrix} a & 0 \\ c & d \end{vmatrix} = ad\), \(D_x = \begin{vmatrix} s & 0 \\ t & d \end{vmatrix} = sd\), and

\[
D_y = \begin{vmatrix} a & s \\ c & t \end{vmatrix} = at-cs,
\]

so \(x = \frac{D_x}{D} = \frac{sd}{ad} = \frac{s}{a}\) and \(y = \frac{D_y}{D} = \frac{at-cs}{ad}\), which is the solution. Note that these solutions agree if \(a = 0\).

\]

63. Evaluating the determinant to show the relationship:

29. \[
A = \begin{bmatrix}
2 & 1 \\
1 & 1 \\
\end{bmatrix}
\]
Augment the matrix with the identity and use row operations to find the inverse:

\[
\begin{bmatrix}
2 & 1 & 0 \\
1 & 1 & 0 \\
\end{bmatrix}
\rightarrow \begin{bmatrix}
1 & 1 & 0 & 1 \\
2 & 1 & 1 & 0 \\
\end{bmatrix}
(\text{Interchange } r_1 \text{ and } r_2)
\rightarrow \begin{bmatrix}
1 & 1 & 0 & 1 \\
0 & -1 & 1 & 2 \\
\end{bmatrix}
(\text{ } R_2 = -2r_1 + r_2 )
\rightarrow \begin{bmatrix}
1 & 1 & 0 & 1 \\
0 & 1 & 1 & -2 \\
\end{bmatrix}
(\text{ } R_1 = -r_2 + r_1)
\rightarrow \begin{bmatrix}
1 & 0 & 1 & -1 \\
0 & 1 & 1 & 2 \\
\end{bmatrix}
(\text{ } R_1 = -r_2 + r_1)
\]
Thus, \[A^{-1} = \begin{bmatrix}
1 & -1 \\
-1 & 2 \\
\end{bmatrix}\].

30. \[
A = \begin{bmatrix}
3 & -1 \\
-2 & 1 \\
\end{bmatrix}
\]
Augment the matrix with the identity and use row operations to find the inverse:

\[
\begin{bmatrix}
3 & -1 & 1 \\
-2 & 1 & 0 \\
\end{bmatrix}
\rightarrow \begin{bmatrix}
1 & 0 & 1 \\
2 & 1 & 0 \\
\end{bmatrix}
(\text{ } R_1 = r_2 + r_1)
\rightarrow \begin{bmatrix}
1 & 0 & 1 \\
0 & 1 & 2 \\
\end{bmatrix}
(\text{ } R_2 = 2r_1 + r_2)
\]
Thus, \[A^{-1} = \begin{bmatrix}
1 & 1 \\
2 & 3 \\
\end{bmatrix}\].
31. \( A = \begin{bmatrix} 6 & 5 \\ 2 & 2 \end{bmatrix} \)

Augment the matrix with the identity and use row operations to find the inverse:

\[
\begin{bmatrix} 6 & 5 & 1 & 0 \\ 2 & 2 & 0 & 1 \end{bmatrix}
\]

\(
\rightarrow \begin{bmatrix} 2 & 2 & 0 & 1 \\ 6 & 5 & 1 & 0 \end{bmatrix}
\)

(Interchange \( r_1 \) and \( r_2 \))

\[
\rightarrow \begin{bmatrix} 2 & 2 & 0 & 1 \\ 0 & -1 & 1 & -3 \end{bmatrix}
\]

\( R_2 = -3r_1 + r_2 \)

\[
\rightarrow \begin{bmatrix} 1 & 1 & 0 & \frac{1}{3} \\ 0 & 1 & -1 & 3 \end{bmatrix}
\]

\( R_1 = \frac{1}{3} r_1 \)

\( R_2 = -r_2 \)

\[
\rightarrow \begin{bmatrix} 1 & 0 & 1 & -\frac{5}{2} \\ 0 & 1 & -1 & 3 \end{bmatrix}
\]

\( R_1 = r_2 + r_1 \)

Thus, \( A^{-1} = \begin{bmatrix} 1 & -\frac{5}{2} \\ -1 & 3 \end{bmatrix} \).

32. \( A = \begin{bmatrix} -4 & 1 \\ 6 & -2 \end{bmatrix} \)

Augment the matrix with the identity and use row operations to find the inverse:

\[
\begin{bmatrix} -4 & 1 & 1 & 0 \\ 6 & -2 & 0 & 1 \end{bmatrix}
\]

\[
\rightarrow \begin{bmatrix} 1 & -\frac{1}{4} & -\frac{1}{4} & 0 \\ 6 & -2 & 0 & 1 \end{bmatrix}
\]

(Interchange \( r_1 \) and \( r_2 \))

\[
\rightarrow \begin{bmatrix} 1 & -\frac{1}{4} & -\frac{1}{4} & 0 \\ 0 & -\frac{1}{2} & \frac{3}{2} & 1 \end{bmatrix}
\]

\( R_2 = -6r_1 + r_2 \)

\[
\rightarrow \begin{bmatrix} 1 & -\frac{1}{4} & -\frac{1}{4} & 0 \\ 0 & 1 & -3 & -2 \end{bmatrix}
\]

\( R_2 = -2r_2 \)

\[
\rightarrow \begin{bmatrix} 1 & 0 & -1 & -\frac{1}{2} \\ 0 & 1 & -3 & -2 \end{bmatrix}
\]

\( R_1 = -\frac{1}{2} r_2 + r \)

Thus, \( A^{-1} = \begin{bmatrix} -1 & -\frac{1}{2} \\ -3 & -2 \end{bmatrix} \).

33. \( A = \begin{bmatrix} 2 & 1 \\ a & a \end{bmatrix} \) where \( a \neq 0 \).

Augment the matrix with the identity and use row operations to find the inverse:

\[
\begin{bmatrix} 2 & 1 & 1 & 0 \\ a & a & 0 & 1 \end{bmatrix}
\]

\[
\rightarrow \begin{bmatrix} 1 & \frac{1}{2} & \frac{1}{2} & 0 \\ a & a & 0 & 1 \end{bmatrix}
\]

\( R_1 = \frac{1}{2} r_1 \)

\[
\rightarrow \begin{bmatrix} 1 & \frac{1}{2} & \frac{1}{2} & 0 \\ 0 & \frac{1}{2}a & -\frac{1}{2}a & 1 \end{bmatrix}
\]

\( R_2 = -ar_1 + r_2 \)

\[
\rightarrow \begin{bmatrix} 1 & \frac{1}{2} & \frac{1}{2} & 0 \\ 0 & 1 & -1 & \frac{2}{a} \end{bmatrix}
\]

\( R_2 = \frac{2}{a} r_2 \)

\[
\rightarrow \begin{bmatrix} 1 & 0 & 1 & -\frac{1}{a} \\ 0 & 1 & -1 & \frac{2}{a} \end{bmatrix}
\]

\( R_1 = -\frac{1}{2} r_2 + r_1 \)

Thus, \( A^{-1} = \begin{bmatrix} 1 & -\frac{1}{2} \\ -1 & \frac{2}{a} \end{bmatrix} \).

34. \( A = \begin{bmatrix} b & 3 \\ b & 2 \end{bmatrix} \) where \( b \neq 0 \).

Augment the matrix with the identity and use row operations to find the inverse:

\[
\begin{bmatrix} b & 3 & 1 & 0 \\ b & 2 & 0 & 1 \end{bmatrix}
\]

\[
\rightarrow \begin{bmatrix} b & 3 & 1 & 0 \\ 0 & -1 & -1 & 1 \end{bmatrix}
\]

\( R_2 = r_1 + r_2 \)

\[
\rightarrow \begin{bmatrix} b & 3 & 1 & 0 \\ 0 & -1 & -1 & 1 \end{bmatrix}
\]

\( R_1 = \frac{1}{b} r_1 \)

\[
\rightarrow \begin{bmatrix} b & 3 & 1 & 0 \\ 0 & 1 & 1 & -1 \end{bmatrix}
\]

\( R_2 = r_2 \)

\[
\rightarrow \begin{bmatrix} b & 3 & 1 & 0 \\ 0 & 1 & 1 & -1 \end{bmatrix}
\]

\( R_1 = -\frac{1}{b} r_2 + r_1 \)

Thus, \( A^{-1} = \begin{bmatrix} -\frac{2}{b} & \frac{3}{b} \\ 1 & -1 \end{bmatrix} \).
Augment the matrix with the identity and use row operations to find the inverse:

\[
\begin{bmatrix}
1 & 1 & 1 & 1 & 0 & 0 \\
1 & 1 & 1 & 1 & 0 & 0 \\
0 & -2 & 1 & 0 & 1 & 0 \\
-2 & -3 & 0 & 0 & 0 & 1
\end{bmatrix} + \begin{bmatrix}
1 & 1 & 1 & 1 & 0 & 0 \\
0 & -2 & 1 & 0 & 1 & 0 \\
0 & -5 & 2 & 2 & 0 & 1 \\
1 & -1 & 1 & 0 & 1 & 0
\end{bmatrix}
\]

\[
\begin{align*}
R_1 &= 2r_1 + r_3 \\
R_2 &= -r_2 \\
R_3 &= 5r_2 + r_3
\end{align*}
\]

Thus, \( A^{-1} = \begin{bmatrix} 3 & -2 & -5 \\ -1 & 1 & 2 \end{bmatrix} \).
38. \[ A = \begin{bmatrix} 3 & 3 & 1 \\ 1 & 2 & 1 \\ 2 & -1 & 1 \end{bmatrix} \]

Augment the matrix with the identity and use row operations to find the inverse:

\[ \begin{bmatrix} 3 & 3 & 1 & | & 1 & 0 & 0 \\ 1 & 2 & 1 & | & 0 & 1 & 0 \\ 2 & -1 & 1 & | & 0 & 0 & 1 \end{bmatrix} \]

\[ \begin{array}{c}
\rightarrow \begin{bmatrix} 1 & 2 & 1 & | & 1 & 0 & 1 \\ 3 & 3 & 1 & | & 1 & 0 & 0 \\ 2 & -1 & 1 & | & 0 & 0 & 1 \end{bmatrix} \\

\rightarrow \begin{bmatrix} 1 & 0 & -3 & | & -1 & 0 & -1 \\ 0 & 1 & 2 & | & -1 & 1 & 0 \\ 0 & 5 & 3 & | & -1 & 0 & 1 \end{bmatrix} \\
\rightarrow \begin{bmatrix} 1 & 0 & -3 & | & -1 & 0 & -1 \\ 0 & 1 & 2 & | & -1 & 1 & 0 \\ 0 & 0 & 3 & | & 1 & 0 & 1 \end{bmatrix} \\

Thus, \( A^{-1} = \begin{bmatrix} \frac{1}{3} & -\frac{4}{3} & \frac{1}{3} \\ \frac{1}{3} & \frac{1}{3} & -\frac{2}{3} \\ \frac{5}{9} & \frac{9}{7} & \frac{3}{7} \end{bmatrix} \).

\[ \begin{bmatrix} 750 & 350 & 80 \\ 800 & 500 & 240 \end{bmatrix} \begin{bmatrix} 100 \\ 150 \\ 200 \end{bmatrix} = \begin{bmatrix} 143,500 \\ 203,000 \end{bmatrix} \]

The city location has a two-month profit of $143,500. The suburban location has a two-month profit of $203,000.

77. a. \[ K = \begin{bmatrix} 2 & 1 & 1 \\ 1 & 1 & 0 \\ 1 & 1 & 1 \end{bmatrix} \]

Augment the matrix with the identity and use row operations to find the inverse:
\[ \begin{bmatrix} 2 & 1 & 1 & 1 & 0 & 0 \\ 1 & 0 & 0 & 1 & 0 & 1 \\ 1 & 1 & 0 & 0 & 1 & 1 \end{bmatrix} \]
\[ \rightarrow \begin{bmatrix} 1 & 0 & 0 & 1 & 0 \\ 2 & 1 & 1 & 1 & 0 & 0 \\ 1 & 1 & 1 & 0 & 0 & 1 \end{bmatrix} \]
\[ \rightarrow \begin{bmatrix} 1 & 1 & 0 & 0 & 1 & 0 \\ 0 & -1 & 1 & 1 & 0 & -2 \end{bmatrix} \]
\[ \rightarrow \begin{bmatrix} 1 & 1 & 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 & -1 & 1 \end{bmatrix} \]

Interchange \( r_1 \) and \( r_2 \)

\[ R_2 = -2r_1 + r_2 \]

\[ R_3 = -r_1 + r_3 \]
\[
\begin{bmatrix}
1 & 1 & 0 \\
0 & 1 & -1 \\
0 & 0 & 1
\end{bmatrix}
\rightarrow
\begin{bmatrix}
0 & 1 & 0 \\
-1 & 2 & 0 \\
0 & -1 & 1
\end{bmatrix}
\quad (R_2 = -r_2)
\]

\[
\begin{bmatrix}
1 & 1 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix}
\rightarrow
\begin{bmatrix}
0 & 1 & 0 \\
-1 & 1 & 1 \\
0 & -1 & 1
\end{bmatrix}
\quad (R_2 = r_2 + r_3)
\]

\[
\begin{bmatrix}
1 & 1 & 0 \\
0 & 0 & 1 \\
1 & 0 & 1
\end{bmatrix}
\rightarrow
\begin{bmatrix}
0 & 1 & -1 \\
1 & 1 & 1 \\
0 & 1 & 0
\end{bmatrix}
\quad (R_1 = r_1 - r_2)
\]

Thus, \( K^{-1} = \begin{bmatrix} 1 & 0 & -1 \\ -1 & 1 & 1 \\ 0 & -1 & 1 \end{bmatrix} \).

### 79. \( A = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \)

\[
\begin{align*}
\begin{bmatrix} a & b \\ c & d \end{bmatrix}
& \rightarrow
\begin{bmatrix}
1 & \frac{b}{a} & \frac{1}{a} \\
0 & d - \frac{bc}{a} & -\frac{c}{a}
\end{bmatrix} \\
& \rightarrow
\begin{bmatrix}
1 & \frac{b}{a} & \frac{1}{a} \\
0 & -\frac{ad - bc}{a} & -\frac{b}{a}
\end{bmatrix} \\
& \rightarrow
\begin{bmatrix}
1 & \frac{b}{a} & \frac{1}{a} \\
0 & 1 & \frac{b}{ad - bc} - \frac{b}{ad - bc}
\end{bmatrix}

\end{align*}
\]

Because

\[
\begin{align*}
a_{11} &= 47(1) + 34(-1) + 33(0) = 13 \\
a_{12} &= 47(0) + 34(1) + 33 = 1 \\
a_{13} &= 47(-1) + 34(1) + 33(1) = 20 \\
a_{21} &= 44(1) + 36(-1) + 27(0) = 8 \\
a_{22} &= 44(0) + 36(1) + 27(-1) = 9 \\
a_{23} &= 44(-1) + 36(1) + 27(1) = 19 \\
a_{31} &= 47(1) + 41(-1) + 20(0) = 6 \\
a_{32} &= 47(0) + 41(1) + 20(-1) = 21 \\
a_{33} &= 47(-1) + 41(1) + 20(1) = 14
\end{align*}
\]

0.4(0.2) + 0.2(0.6) + 0.1(0.2) = 0.22 \\
0.4(0.1) + 0.2(0.5) + 0.1(0.4) = 0.18 \\
0.5(0.4) + 0.6(0.5) + 0.5(0.1) = 0.55 \\
0.5(0.2) + 0.6(0.6) + 0.5(0.2) = 0.56 \\
0.5(0.1) + 0.6(0.5) + 0.5(0.4) = 0.55 \\
0.5(0.1) + 0.2(0.5) + 0.4(0.1) = 0.18 \\

Section 8.5: Partial Fraction Decomposition

13. Find the partial fraction decomposition:
\[
\frac{4}{x(x-1)} = \frac{A}{x} + \frac{B}{x-1}
\]
\[
x(x-1)\left(\frac{4}{x(x-1)}\right) = x(x-1)\left(\frac{A}{x} + \frac{B}{x-1}\right)
\]
\[
4 = A(x-1) + Bx
\]
Let \( x = 1 \), then \( 4 = A(0) + B \)
\[
B = 4
\]
Let \( x = 0 \), then \( 4 = A(-1) + B(0) \)
\[
A = -4
\]
\[
\frac{4}{x(x-1)} = \frac{-4}{x} + \frac{4}{x-1}
\]

14. Find the partial fraction decomposition
\[
\frac{3x}{(x+2)(x-1)} = \frac{A}{x+2} + \frac{B}{x-1}
\]
Multiplying both sides by \((x+2)(x-1)\), we obtain:
\[
3x = A(x-1) + B(x+2)
\]
Let \( x = 1 \), then \( 3(1) = A(0) + B(3) \)
\[
3B = 3
\]
\[
B = 1
\]
Let \( x = -2 \), then \( 3(-2) = A(-3) + B(0) \)
\[
-3A = -6
\]
\[
A = 2
\]
\[
\frac{3x}{(x+2)(x-1)} = \frac{2}{x+2} + \frac{1}{x-1}
\]

15. Find the partial fraction decomposition:
\[
\frac{1}{x(x^2+1)} = \frac{A}{x} + \frac{Bx+C}{x^2+1}
\]
\[
x(x^2+1)\left(\frac{1}{x(x^2+1)}\right) = x(x^2+1)\left(\frac{A}{x} + \frac{Bx+C}{x^2+1}\right)
\]
\[
1 = A(x^2+1) + (Bx+C)x
\]
Let \( x = 0 \), then \( 1 = A(0^2+1) + (B(0)+C)(0) \)
\[
A = 1
\]
Let \( x = 1 \), then \( 1 = A(1^2+1) + (B(1)+C)(1) \)
\[
1 = 2A + B + C
\]
\[
1 = 2(1) + B + C
\]
\[
B + C = -1
\]
Let \( x = -1 \), then
\[
1 = A((-1)^2+1) + (B(-1)+C)(-1)
\]
\[
1 = A(1) + (-B + C)(-1)
\]
\[
1 = 2A + B - C
\]
\[
1 = 2(1) + B - C
\]

\[
1 = 5A + (B+C)(2)
\]
\[
1 = 5\left(\frac{1}{5}\right) + 2B + 2C
\]
\[
1 = 1 + 2B + 2C
\]
\[
0 = 2B + 2C
\]
\[
0 = B + C
\]
Let \( x = 0 \), then \( 1 = A(0^2+4) + (B(0)+C)(0+1) \)
\[
1 = 4A + C
\]
\[
1 = 4\left(\frac{1}{5}\right) + C
\]
\[
1 = \frac{4}{5} + C
\]
\[
C = \frac{1}{5}
\]
Since \( B + C = 0 \), we have that \( B + \frac{1}{5} = 0 \)
\[
B = -\frac{1}{5}

\[
\frac{1}{(x+1)(x^2+4)} = \frac{\frac{1}{5}}{x+1} + \frac{-\frac{1}{5}x + \frac{1}{5}}{x^2+4}
\]

\]

26. Find the partial fraction decomposition:
\[
\frac{x^2 + x}{(x + 2)(x - 1)^2} = \frac{A}{x + 2} + \frac{B}{x - 1} + \frac{C}{(x - 1)^2}
\]
Multiplying both sides by \((x + 2)(x - 1)^2\), we obtain:
\[
x^2 + x = A(x - 1)^2 + B(x + 2)(x - 1) + C(x + 2)

Let \( x = -2 \), then
\[
(-2)^2 + (-2) = A(-2 - 1)^2 + B(-2 + 2)(-2 - 1) + C(-2 + 2)

\[
\frac{x + 4}{x^2(x^2 + 4)} = \frac{A}{x} + \frac{B}{x^2} + \frac{Cx + D}{x^2 + 4}
\]
Multiplying both sides by \(x^2(x^2 + 4)\), we obtain:
\[
x + 4 = A(x^2 + 4) + B(x^2 + 4) + (Cx + D)x^2
\]
Let \( x = 0 \), then
\[
0 + 4 = A(0^2 + 4) + B(0^2 + 4) + (C(0) + D)(0)^2

\]
\[6 = 16A + 8B + 8C + 4D
\]
\[6 = 16A + 8 + 8C + 4D

\[16A + 8C + 4D = -2
\]
Solve the system of equations:

\[2D = -2
\]
\[D = -1
\]
\[5A + C + D = 0
\]
\[C = 1 - 5A
\]
\[16A + 8(1 - 5A) + 4(-1) = -2
\]
\[16A - 80A - 4 = -2

28. Find the partial fraction decomposition:

\[
\frac{10x^2 + 2x}{(x-1)^2(x^2 + 2)} = \frac{A}{x-1} + \frac{B}{(x-1)^2} + \frac{Cx+D}{x^2 + 2}
\]

Multiply both sides by \((x-1)^2(x^2 + 2)\):

\[
10x^2 + 2x = A(x-1)(x^2 + 2) + B(x^2 + 2) + (Cx+D)(x-1)^2
\]

Let \(x = 1\), then

\[
10(1)^2 + 2(1) = A(1-1)((-1)^2 + 2) + B((1)^2 + 2) + (C(1)+D)((-1)^2)
\]

\[12 = 3B\]

Let \(x = 0\), then

\[
10(0)^2 + 2(0) = A(0-1)(0^2 + 2) + B(0^2 + 2) + (C(0)+D)(0-1)^2
\]

\[12 = 3B\]

\[B = 4\]

Let \(x = -1\), then

\[
10(-1)^2 + 2(-1) = A(-1-1)((-1)^2 + 2) + B((-1)^2 + 2) + (C(-1)+D)(-1-1)^2
\]

\[8 = -6A + 3B - 4C + 4D\]

\[8 = -6A + 12 - 4C + 4D\]

\[-6A - 4C + 4D = -4\]

Let \(x = 2\), then

\[
10(2)^2 + 2(2) = A(2-1)(2^2 + 2) + B(2^2 + 2) + (C(2)+D)(2-1)^2
\]

\[44 = 6A + 6B + 2C + D\]

\[44 = 6A + 24 + 2C + D\]

\[6A + 2C + D = 20\]

Solve the system of equations (Substitute for \(D\)):

\[D = 2A - 8\]

\[-6A - 4C + 4D = -4\]

\[-6A - 4C + 4(2A - 8) = -4\]

\[2A - 4C = 28\]

\[A - 2C = 14\]

\[A - 2C = 14\]

\[8A + 2C = 28\]

Add the equations and solve:

\[A = 14\]

\[C = -\frac{14}{3}\]

\[D = 2A - 8 = 2\left(\frac{14}{3}\right) - 8 = \frac{4}{3}\]

\[10x^2 + 2x = \frac{\frac{14}{3} + 4}{x-1} + \frac{-\frac{14}{3}x + \frac{4}{3}}{x^2 + 2}\]

29. Find the partial fraction decomposition:

\frac{x^2 + 2x + 3}{(x+1)(x^2 + 2x + 4)} = \frac{A}{x+1} + \frac{Bx + C}{x^2 + 2x + 4}
\]

Multiplying both sides by \((x+1)(x^2 + 2x + 4)\), we obtain:

\[x^2 + 2x + 3 = A(x^2 + 2x + 4) + (Bx + C)(x+1)\]

Let \(x = -1\), then

\[(-1)^2 + 2(-1) + 3 = A((-1)^2 + 2(-1) + 4) + (B(-1) + C)(-1+1)\]

\[2 = 3A\]

\[A = \frac{2}{3}\]

Let \(x = 0\), then

\[0^2 + 2(0) + 3 = A(0^2 + 2(0) + 4) + (B(0) + C)(0+1)\]

\[3 = 4A + C\]

\[3 = 4\left(\frac{2}{3}\right) + C\]

\[C = \frac{1}{3}\]

Let \(x = 1\), then

\[1^2 + 2(1) + 3 = A(1^2 + 2(1) + 4) + (B(1) + C)(1+1)\]

\[6 = 7A + 2B + 2C\]

\[6 = 7\left(\frac{2}{3}\right) + 2B + 2\left(\frac{1}{3}\right)\]

\[2B = 6 - \frac{14}{3} - \frac{2}{3} = \frac{2}{3}\]

\[B = \frac{1}{3}\]

\[\frac{x^2 + 2x + 3}{(x+1)(x^2 + 2x + 4)} = \frac{\frac{7}{3}}{x+1} + \frac{\frac{4}{3}x + \frac{1}{3}}{x^2 + 2x + 4}\]

\]

Multiplying both sides by 
\[x(x^2 + 3x + 3)(x + 1)(x^2 + 2x + 4),\]
we obtain:

\[x^2 - 11x - 18 = A(x^2 + 3x + 3) + (Bx + C)x\]

Let \(x = 0\), then 
\[0^2 - 11(0) - 18 = A(0^2 + 3(0) + 3) + (B(0) + C)(0)\]
\[-18 = 3A\]
\[A = -6\]

Let \(x = 1\), then 
\[1^2 - 11(1) - 18 = A(1^2 + 3(1) + 3) + (B(1) + C)(1)\]
\[-28 = 7A + B + C\]
\[-28 = 7(-6) + B + C\]
\[B + C = 14\]

Let \(x = -1\), then 
\[(-1)^2 - 11(-1) - 18 = A((-1)^2 + 3(-1) + 3) + (B(-1) + C)(-1)\]
\[-6 = A + B - C\]
\[-6 = -6 + B - C\]
\[B - C = 0\]

Add the last two equations and solve:
\[B + C = 14\]
\[B - C = 0\]
\[2B = 14\]
\[B = 7\]
\[B + C = 14\]
\[7 + C = 14\]
\[C = 7\]

\[
\frac{x^2 - 11x - 18}{x(x^2 + 3x + 3)} = \frac{-6}{x} + \frac{7x + 7}{x^2 + 3x + 3}
\]

**31.** Find the partial fraction decomposition:

\]

Multiplying both sides by 
\[(3x - 2)(2x + 1),\]
we obtain: 
\[x = A(2x + 1) + B(3x - 2)\]

Let \(x = -\frac{1}{2}\), then 
\[-\frac{1}{2} = A(2(-1/2) + 1) + B(3(-1/2) - 2)\]
\[-\frac{1}{2} = -\frac{7}{2}B\]
\[B = \frac{1}{7}\]

Let \(x = \frac{2}{3}\), then 
\[\frac{2}{3} = A\left(\frac{2}{3}2/3 + 1\right) + B\left(3\left(2/3\right) - 2\right)\]
\[\frac{2}{3} = \frac{7}{3}A\]
\[A = \frac{2}{7}\]

\[
\frac{1}{(3x - 2)(2x + 1)} = \frac{\frac{2}{7}}{3x - 2} + \frac{\frac{1}{7}}{2x + 1}

Chapter 8: Systems of Equations and Inequalities

39. Perform synthetic division to find a factor:

\[
\begin{array}{c|cc}
2 & 1 & -4 & 5 & -2 \\
\hline
 & 1 & -2 & 1 & 0 \\
\end{array}
\]

\[
x^3 - 4x^2 + 5x - 2 = (x - 2)(x^2 - 2x + 1) = (x - 2)(x - 1)^2
\]

Find the partial fraction decomposition:

\[
\frac{x^2}{x^3 - 4x^2 + 5x - 2} = \frac{A}{x - 2} + \frac{B}{x - 1} + \frac{C}{(x - 1)^2}
\]

Multiplying both sides by \((x - 2)(x - 1)^2\), we obtain:

\[
x^2 + 1 = A(x + 3)(x - 1)^2 + B(x + 3)(x - 1) + C(x + 3)
\]

Let \(x = -3\), then

\[
(-3)^2 + 1 = A(-3 - 1)^2 + B(-3 + 3)(-3 - 1) + C(-3 + 3)
\]

\[
10 = 16A + 16B + 8C
\]

\[
A = \frac{5}{8}
\]

Let \(x = 1\), then

\[
1^2 + 1 = A(1 - 1)^2 + B(1 + 3)(1 - 1) + C(1 + 3)
\]

\[
2 = 4C
\]

\[
C = \frac{1}{2}
\]

Let \(x = 0\), then

\[
0^2 + 1 = A(0 - 1)^2 + B(0 + 3)(0 - 1) + C(0 + 3)
\]

\[
1 = A - 3B + 3C
\]

\[
1 = \frac{5}{8} - 3B + 3\left(\frac{1}{2}\right)
\]

\[
3B = \frac{9}{8}
\]

\[
B = \frac{3}{8}
\]

\[
\frac{x^2 + 1}{x^3 + x^2 - 5x + 3} = \frac{\frac{5}{8}}{x + 3} + \frac{\frac{3}{8}}{x - 1} + \frac{\frac{1}{2}}{(x - 1)^2}
\]

40. Perform synthetic division to find a factor:

\[
\begin{array}{c|ccc}
1 & 1 & -5 & 3 \\

\end{array}
\]

\[
x^3 + 5x^2 - 3x - 3 = (x - 1)(x^2 + 2x - 3) = (x + 3)(x - 1)^2
\]

Find the partial fraction decomposition:

\[
\frac{x^2 + 1}{x^3 + x^2 - 5x + 3} = \frac{Ax + B}{(x^2 + 16)^3} + \frac{Cx + D}{(x^2 + 16)^2} + \frac{Ex + F}{(x^2 + 16)}
\]

Multiplying both sides by \((x^2 + 16)^3\), we obtain:

\[
x^3 = (Ax + B)(x^2 + 16)^2 + (Cx + D)(x^2 + 16) + Ex + F
\]

\[
x^3 = (Ax + B)(x^4 + 32x^2 + 256) + Cx^3 + Dx^2 + 16Cx + 16D + Ex + F
\]

\[
x^3 = Ax^5 + Bx^4 + 32Ax^3 + 32Bx^2 + 256Ax + 256B + Cx^3 + Dx^2 + 16Cx + 16D + Ex + F
\]
Section 8.5: Partial Fraction Decomposition

\[ x^3 = Ax^5 + Bx^4 + (32A + C)x^3 + (32B + D)x^2 + (256A + 16C + E)x + (256B + 16D + F) \]

\[ A = 0; \quad B = 0; \quad 32A + C = 1 \]
\[ 32(0) + D = 1 \]
\[ 32B + D = 0 \]
\[ 256(0) + D = 0 \]
\[ 256B + 16D + F = 0 \]
\[ 256(0) + 16(0) + F = 0 \]

Multiplying both sides by \((x^2 + 4)^3\), we obtain:
\[ x^2 = (Ax + B)(x^2 + 4)^2 + (Cx + D)(x^2 + 4)^2 + (Ex + F)(x^2 + 4)^3 \]
\[ x^2 = (Ax + B)(x^4 + 8x^2 + 16) + Cx^3 + Dx^2 + 4Cx + 4D + Ex + F \]
\[ x^2 = Ax^5 + Bx^4 + 8Ax^3 + 8Bx^2 + 16Ax + 16B + Cx^3 + Dx^2 + 4Cx + 4D + Ex + F \]
\[ x^2 = Ax^5 + Bx^4 + (8A + C)x^3 + (8B + D)x^2 + (16A + 4C + E)x + (16B + 4D + F) \]
\[ A = 0; \quad B = 0; \quad 8A + C = 0 \]
\[ 8(0) + C = 0 \]
\[ C = 0 \]
\[ 8B + D = 1 \]
\[ 16A + 4C + E = 0 \]
\[ 8(0) + D = 1 \]
\[ 16(0) + 4(0) + E = 0 \]
\[ D = 1 \]
\[ E = 0 \]
\[ 16B + 4D + F = 0 \]
\[ 16(0) + 4(1) + F = 0 \]
\[ F = -4 \]
\[ \frac{x^2}{(x^2 + 4)^3} = \frac{1}{(x^2 + 4)^2} + \frac{-4}{(x^2 + 4)^3} \]

43. Find the partial fraction decomposition:

\[ 4 = A(x + 3) + B(x - 3) \]
Let \( x = -\frac{1}{2} \), then
\[ 4 = \frac{7}{2}B \]
\[ B = -\frac{7}{4} \]
Let \( x = 3 \), then
\[ 4 = A(2(3) + 1) + B(3 - 3) \]
\[ 4 = 7A \]
\[ A = \frac{4}{7} \]
\[ \frac{4}{2x^2 - 5x - 3} = \frac{4}{x - 3} + \frac{-8}{2x + 1} \]

44. Find the partial fraction decomposition:
\[ \frac{4x}{2x^2 + 3x - 2} = \frac{4x}{(x + 2)(2x - 1)} = \frac{A}{x + 2} + \frac{B}{2x - 1} \]

Multiplying both sides by \((x + 2)(2x - 1)\), we obtain:
\[ 4x = A(2x - 1) + B(x + 2) \]
Let \( x = \frac{1}{2} \), then
\[ 4\left(\frac{1}{2}\right) = A\left(2\left(\frac{1}{2}\right) - 1\right) + B\left(\frac{1}{2} + 2\right) \]
\[ 2 = \frac{5}{3}B \]
\[ B = \frac{4}{5} \]
Let \( x = -2 \), then
\[ 4(-2) = A(2(-2) - 1) + B(-2 + 2) \]
\[ -8 = -5A \]
\[ A = \frac{8}{5} \]

\[ 9 = 54C \]
\[ C = \frac{1}{6} \]
Let \( x = -3 \), then
\[ 2(-3) + 3 = A(-3)(-3 - 3)(-3 + 3) + B(-3 - 3)(-3 + 3) + C(-3)^2(-3 + 3) + D(-3)^2(-3 - 3) \]
\[ -3 = -54D \]
\[ D = \frac{1}{18} \]
Let \( x = 1 \), then
\[ 2 \cdot 1 + 3 = A \cdot 1(1 - 3)(1 + 3) + B(1 - 3)(1 + 3) + C \cdot 1^2(1 + 3) + D \cdot 1^2(1 - 3) \]
\[ 5 = -8A - 8B + 4C - 2D \]
\[ 5 = -8A - 8(-1/3) + 4(1/6) - 2(1/18) \]
\[ 5 = -8A + \frac{8}{3} + \frac{2}{3} - \frac{1}{9} \]
\[ -8A = 16 \]
\[ A = -\frac{2}{9} \]
\[ \frac{2x + 3}{x^4 - 9x^2} = \frac{-\frac{2}{9} x + \frac{1}{9} x^2 + \frac{1}{6} x + \frac{1}{18}}{x^3 x} + \frac{-\frac{2}{9}}{x + 3} \]

46. Find the partial fraction decomposition:

\[ 9 = 4A - 4B - 4D \]
\[ 9 = 4\left(\frac{13}{24}\right) - 4\left(-\frac{13}{24}\right) - 4D \]
\[ 4D = \frac{14}{3} \]
\[ D = -\frac{7}{6} \]
Let \( x = 1 \), then

\]
Multiply each side of the second equation by 2 and add the equations to eliminate \(y\):
\[\frac{3}{(1)^2} + \frac{1}{y^2} = 7 \implies \frac{1}{y^2} = 4 \implies y^2 = \frac{1}{4}\]
\[x^2 = 1 \implies x = \pm 1\]

If \(x = 1\):
\[\frac{3}{(1)^2} + \frac{1}{y^2} = 7 \implies \frac{1}{y^2} = 4 \implies y^2 = \frac{1}{4}\]
\[y = \pm \frac{1}{2}\]

If \(x = -1\):
\[\frac{3}{(-1)^2} + \frac{1}{y^2} = 7 \implies \frac{1}{y^2} = 4 \implies y^2 = \frac{1}{4}\]
\[y = \pm \frac{1}{2}\]

Solutions:
\((1, \frac{1}{2}), (1, -\frac{1}{2}), (-1, \frac{1}{2}), (-1, -\frac{1}{2})\)
Chapter 8: Systems of Equations and Inequalities

44. \[
\begin{align*}
\frac{2}{x^2} - \frac{3}{y^2} + 1 &= 0 \\
\frac{6}{x^2} - \frac{7}{y^2} + 2 &= 0 \\
\frac{2}{x^2} - \frac{3}{y^2} &= -1 \\
\frac{6}{x^2} - \frac{7}{y^2} &= -2
\end{align*}
\]
Multiply each side of the first equation by \(-3\) and add the equations to eliminate \(x\):

\[
\begin{align*}
\frac{-6}{y^2} + \frac{9}{y^2} &= 3 \\
\frac{6}{x^2} - \frac{7}{y^2} &= -2
\end{align*}
\]
\[
\frac{2}{y^2} = 1
\]
\[
y^2 = 2
\]
\[
y = \pm \sqrt{2}
\]
If \(y = \sqrt{2}\):
\[
\frac{2}{x^2} - \frac{3}{\sqrt{2}} = -1 \implies \frac{2}{x^2} = \frac{1}{2}
\]
\[
x^2 = 4 \implies x = \pm 2
\]
If \(y = -\sqrt{2}\):
\[
\frac{2}{x^2} - \frac{3}{-\sqrt{2}} = -1 \implies \frac{2}{x^2} = \frac{1}{2}
\]
\[
x^2 = 4 \implies x = \pm 2
\]
Solutions:
\((2, \sqrt{2}), (2, -\sqrt{2}), (-2, \sqrt{2}), (-2, -\sqrt{2})\)

46. Add the equations to eliminate \(y\):
\[
\begin{align*}
\frac{1}{x^4} - \frac{1}{y^4} &= 1 \\
\frac{1}{x^4} + \frac{1}{y^4} &= 4
\end{align*}
\]
\[
\begin{align*}
\frac{2}{x^4} &= 5 \\
x^4 &= \frac{2}{5}
\end{align*}
\]
\[
x = \pm \sqrt[4]{\frac{2}{5}}
\]
If \(x = \sqrt[4]{\frac{2}{5}}\):
\[
\frac{1}{x^4} + \frac{1}{y^4} = 4 \implies \frac{1}{y^4} = \frac{3}{2}
\]
\[
y^4 = \frac{2}{3} \implies y = \pm \sqrt[6]{\frac{2}{3}}
\]
If \(x = -\sqrt[4]{\frac{2}{5}}\):
\[
\frac{1}{x^4} + \frac{1}{y^4} = 4 \implies \frac{1}{y^4} = \frac{3}{2}
\]
\[
y^4 = \frac{2}{3} \implies y = \pm \sqrt[6]{\frac{2}{3}}
\]
Solutions:
\(\left(\sqrt[4]{\frac{2}{5}}, \sqrt[3]{\frac{2}{3}}\right), \left(-\sqrt[4]{\frac{2}{5}}, -\sqrt[3]{\frac{2}{3}}\right), \left(-\sqrt[6]{\frac{2}{3}}, \sqrt[6]{\frac{2}{3}}\right), \left(-\sqrt[6]{\frac{2}{3}}, -\sqrt[6]{\frac{2}{3}}\right)\)

47. \[
\begin{align*}
x^2 - 3xy + 2y^2 &= 0 \\
x^2 + xy &= 6
\end{align*}
\]
Subtract the second equation from the first to eliminate the \(x^2\) term.
\[-4xy + 2y^2 = -6
\]
\[2xy - y^2 = 3
\]
Since \(y \neq 0\), we can solve for \(x\) in this equation to get
\[x = y^2 + 3, \quad y \neq 0
\]
Now substitute for \(x\) in the second equation and solve for \(y\).
Section 8.6: Systems of Nonlinear Equations

48. \[
\begin{align*}
  x^2 + xy &= 6 \\
  \left(\frac{y^2 + 3}{2y}\right)^2 + \left(\frac{y^2 + 3}{2y}\right)y &= 6 \\
  \frac{y^4 + 6y^2 + 9}{4y^2} + \frac{y^2 + 3}{2} &= 6 \\
  y^4 + 6y^2 + 9 + 2y^4 + 6y^2 &= 24y^2 \\
  3y^4 - 12y^2 + 9 &= 0 \\
  y^4 - 4y^2 + 3 &= 0 \\
  (y^2 + 3)(y^2 - 1) &= 0 \\
  \end{align*}
\]

Thus, \( y = \pm \sqrt{3} \) or \( y = \pm 1 \).

If \( y = 1 \): \( x = 2 \cdot 1 = 2 \)
If \( y = -1 \): \( x = 2(-1) = -2 \)
If \( y = \sqrt{3} \): \( x = \sqrt{3} \)
If \( y = -\sqrt{3} \): \( x = -\sqrt{3} \)

Solutions: \((2, 1), (-2, -1), (\sqrt{3}, \sqrt{3}), (-\sqrt{3}, -\sqrt{3})\)

49. \[
\begin{align*}
  y^2 + y + x^2 - x - 2 &= 0 \\
  y + 1 + \frac{x - 2}{y} &= 0 \\
  \end{align*}
\]

Multiply each side of the second equation by \(-y\) and add the equations to eliminate \(y\):
\[
\begin{align*}
  y^2 + y + x^2 - x - 2 &= 0 \\
  -y^2 - y - x + 2 &= 0 \\
  x^2 - 2x &= 0 \\
  x(x - 2) &= 0 \\
  x &= 0 \text{ or } x = 2 \\
  \end{align*}
\]

If \( x = 0 \):
\[
\begin{align*}
  y^2 + y + 0^2 - 0 - 2 &= 0 \quad \Rightarrow \quad y^2 + y - 2 = 0 \\
  \Rightarrow (y + 2)(y - 1) &= 0 \quad \Rightarrow \quad y = -2 \text{ or } y = 1 \\
  \end{align*}
\]

If \( x = 2 \):
\[
\begin{align*}
  y^2 + y + 2^2 - 2 - 2 &= 0 \quad \Rightarrow \quad y^2 + y = 0 \\
  \Rightarrow \quad y(y + 1) &= 0 \quad \Rightarrow \quad y = 0 \text{ or } y = -1 \\
  \end{align*}
\]

Note: \( y \neq 0 \) because of division by zero.

Solutions: \((0, -2), (0, 1), (2, -1)\)

50. \[
\begin{align*}
  x^3 - 2x^2 + y^2 + 3y - 4 &= 0 \\
  x - 2 + \frac{y^2 - y}{x} &= 0 \\
  \end{align*}
\]

Multiply each side of the second equation by \(-x^2\) and add the equations to eliminate \(x\):
\[
\begin{align*}
  x^3 - 2x^2 + y^2 + 3y - 4 &= 0 \\
  -x^3 + 2x^2 - y^2 + y &= 0 \\
  4y - 4 &= 0 \\
  y &= 1 \\
  \end{align*}
\]

If \( y = 1 \):
\[
\begin{align*}
  x^3 - 2x^2 + 1^2 + 3 \cdot 1 - 4 &= 0 \quad \Rightarrow \quad x^3 - 2x^2 = 0 \\
  \Rightarrow \quad x^2(x - 2) &= 0 \quad \Rightarrow \quad x = 0 \text{ or } x = 2 \\
  \end{align*}
\]

Note: \( x \neq 0 \) because of division by zero.

Solution: \((2, 1)\)
51. Rewrite each equation in exponential form:

\[
\begin{align*}
\log_x y &= 3 \quad \Rightarrow \quad y = x^3 \\
\log_x (4y) &= 5 \quad \Rightarrow \quad 4y = x^5
\end{align*}
\]

Substitute the first equation into the second and solve:

\[
\begin{align*}
4x^3 &= x^5 \\
x^5 - 4x^3 &= 0 \\
x^3 (x^2 - 4) &= 0 \\
x^3 &= 0 \quad \text{or} \quad x^2 = 4 \Rightarrow x = 0 \quad \text{or} \quad x = \pm 2
\end{align*}
\]

The base of a logarithm must be positive, thus \(x \neq 0\) and \(x \neq -2\).

If \(x = 2\):

\[
y = 2^3 = 8
\]

Solution: \((2, 8)\)

52. Rewrite each equation in exponential form:

\[
\begin{align*}
\log_x (2y) &= 3 \quad \Rightarrow \quad 2y = x^3 \\
\log_x (4y) &= 2 \quad \Rightarrow \quad 4y = x^2
\end{align*}
\]

Multiply the first equation by 2 then substitute the first equation into the second and solve:

\[
\begin{align*}
2x^3 &= x^2 \\
2x^3 - x^2 &= 0 \\
x^2 (2x-1) &= 0 \\
x^2 &= 0 \quad \text{or} \quad x = \frac{1}{2} \Rightarrow x = \frac{1}{2} \quad \text{or} \quad x = 0
\end{align*}
\]

The base of a logarithm must be positive, thus \(x \neq 0\).

If \(x = \frac{1}{2}\):

\[
y = \left(\frac{1}{2}\right)^2 = \frac{1}{4} \quad \Rightarrow \quad y = \frac{1}{16}
\]

Solution: \(\left(\frac{1}{2}, \frac{1}{16}\right)\)

53. Rewrite each equation in exponential form:

\[
\begin{align*}
\ln x &= 4 \ln y \quad \Rightarrow \quad x = e^{4 \ln y} = e^{\ln y^4} = y^4 \\
\log_3 x &= 2 + 2 \log_3 y \\
x &= 3^{2+2 \log_3 y} = 3^2 \cdot 3^{2 \log_3 y} = 3^2 \cdot 3^{\log_3 y^2} = 9y^2
\end{align*}
\]

So we have the system

\[
\begin{align*}
x &= y^4 \\
x &= 9y^2
\end{align*}
\]

Therefore we have:

\[
\begin{align*}
9y^2 &= y^4 \quad \Rightarrow \quad 9y^2 - y^4 = 0 \quad \Rightarrow \quad y^2 (9 - y^2) = 0 \\
y^2 &= 0 \quad \text{or} \quad y = \pm 3
\end{align*}
\]

Since \(\ln y\) is undefined when \(y \leq 0\), the only solution is \(y = 3\).

If \(y = 3\):

\[
x = y^4 \quad \Rightarrow \quad x = 3^4 = 81
\]

Solution: \((81, 3)\)

54. Rewrite each equation in exponential form:

\[
\begin{align*}
\ln x &= 5 \ln y \quad \Rightarrow \quad x = e^{5 \ln y} = e^{\ln y^5} = y^5 \\
\log_2 x &= 3 + 2 \log_2 y \\
x &= 2^{3+2 \log_2 y} = 2^3 \cdot 2^{2 \log_2 y} = 2^3 \cdot 2^{\log_2 y^2} = 8y^2
\end{align*}
\]

So we have the system

\[
\begin{align*}
x &= y^5 \\
x &= 8y^2
\end{align*}
\]

Therefore we have

\[
\begin{align*}
8y^2 &= y^5 \\
8y^2 - y^5 &= 0 \\
y^2 (8 - y^3) &= 0 \\
y &= 0 \quad \text{or} \quad 8 - y^3 = 0 \Rightarrow y = 2
\end{align*}
\]

Since \(\ln y\) is undefined when \(y \leq 0\), the only solution is \(y = 2\).

If \(y = 2\):

\[
x = y^5 \quad \Rightarrow \quad x = 2^5 = 32
\]

Solution: \((32, 2)\)

55. Rewrite each equation in exponential form:

\[
\begin{align*}
x^2 + x + y^2 - 3y + 2 &= 0 \\
x + 1 + \frac{y^2 - y}{x} &= 0 \\
(x + \frac{1}{2})^2 + (y - \frac{3}{2})^2 &= \frac{1}{2} \\
(x + \frac{1}{2})^2 + (y - \frac{1}{2})^2 &= \frac{1}{2}
\end{align*}
\]

Therefore we have:

\[
\begin{align*}
x^2 + x + y^2 - 3y + 2 &= 0 \\
x + 1 + \frac{y^2 - y}{x} &= 0 \\
(x + \frac{1}{2})^2 + (y - \frac{3}{2})^2 &= \frac{1}{2} \\
(x + \frac{1}{2})^2 + (y - \frac{1}{2})^2 &= \frac{1}{2}
\end{align*}
\]
56. \[ \begin{align*} y^2 + y + x^2 - x - 2 &= 0 \\ y + 1 + \frac{x - 2}{y} &= 0 \\ \left(\frac{x - 1}{2}\right)^2 + \left(\frac{y + 1}{2}\right)^2 &= \frac{5}{2} \\ x &= -\left(\frac{y + 1}{2}\right)^2 + \frac{2}{3} \\ y + 1 + \frac{x - 2}{y} &= 0 \\ y = \frac{1}{2} \\ \left(\frac{1}{2}, -\frac{1}{2}\right) & \quad (2, -1) \\ x^2 - x + y^2 + y - 2 &= 0 \end{align*} \]

57. Solve the first equation for \( x \), substitute into the second equation and solve:
\[ \begin{align*} x + 2y &= 0 \Rightarrow x = -2y \\ \left(\frac{x - 1}{2}\right)^2 + (y - 1)^2 &= 5 \\ (-2y - 1)^2 + (y - 1)^2 &= 5 \\ 4y^2 + 4y + 1 + y^2 - 2y + 1 &= 5 \\ 5y^2 + 2y - 3 &= 0 \\ (5y - 3)(y + 1) &= 0 \\ y &= \frac{3}{5} \quad \text{or} \quad y = -1 \\ x &= -\frac{6}{5} \quad \text{or} \quad x = 2 \end{align*} \]

The points of intersection are \( \left(\frac{6}{5}, \frac{3}{5}\right), (2, -1) \).

58. Solve the first equation for \( x \), substitute into the second equation and solve:
\[ \begin{align*} x + 2y + 6 &= 0 \Rightarrow x = -2y - 6 \\ (x + 1)^2 + (y + 1)^2 &= 5 \\ (-2y - 6 - 1)^2 + (y + 1)^2 &= 5 \\ 4y^2 + 20y + 25 + y^2 + 2y + 1 &= 5 \\ 5y^2 + 22y + 21 &= 0 \\ (5y + 7)(y + 3) &= 0 \\ y &= -\frac{7}{5} \quad \text{or} \quad y = -3 \\ x &= -\frac{16}{5} \quad \text{or} \quad x = 0 \end{align*} \]

The points of intersection are \( \left(-\frac{16}{5}, -\frac{7}{5}\right), (0, -3) \).

59. Complete the square on the second equation.
\[ \begin{align*} y^2 + 4y + 4 &= x - 1 + 4 \\ (y + 2)^2 &= x + 3 \\ (x - 1)^2 + x + 3 &= 4 \\ x^2 - 2x + 1 + x + 3 &= 4 \\ x^2 - x &= 0 \\ x(x - 1) &= 0 \\ x &= 0 \quad \text{or} \quad x = 1 \end{align*} \]

If \( x = 0 \), \( (y + 2)^2 = 0 + 3 \)
\[ y + 2 = \pm\sqrt{3} \Rightarrow y = -2 \pm \sqrt{3} \]

If \( x = 1 \), \( (y + 2)^2 = 1 + 3 \)
\[ y + 2 = \pm 2 \Rightarrow y = -2 \pm 2 \]

The points of intersection are \( (0, -2 - \sqrt{3}), (0, -2 + \sqrt{3}), (1, -4), (1, 0) \).
Chapter 8: Systems of Equations and Inequalities

60. Complete the square on the second equation, substitute into the first equation and solve:

\[
\begin{align*}
(x+2)^2 + (y-1)^2 &= 4 \\
y^2 - 2y - x - 5 &= 0 \\
x^2 + 4y - x + 1 &= 0
\end{align*}
\]

\[
\begin{align*}
(y-1)^2 &= x + 6 \\
(x+2)^2 + x + 6 &= 4 \\
x^2 + 4x + 4 + x + 6 &= 4 \\
x^2 + 5x + 6 &= 0 \\
(x+2)(x+3) &= 0
\end{align*}
\]

\[
\begin{align*}
x &= -2 \quad \text{or} \quad x = -3
\end{align*}
\]

If \(x = -2\):

\[
(y-1)^2 = -2 + 6 \quad \Rightarrow \quad y - 1 = \pm 2
\]

\[
\Rightarrow \quad y = -1 \quad \text{or} \quad y = 3
\]

If \(x = -3\):

\[
(y-1)^2 = -3 + 6 \quad \Rightarrow \quad y - 1 = \pm \sqrt{3}
\]

\[
\Rightarrow \quad y = 1 \pm \sqrt{3}
\]

The points of intersection are:

\((-3, 1 - \sqrt{3}), (-3, 1 + \sqrt{3}), (-2, -1), (-2, 3)\).

61. Solve the first equation for \(x\), substitute into the second equation and solve:

(y^2 - 4)^2 &= 0 \\
y^2 - 4 &= 0 \\
y^2 &= 4 \\
y &= \pm 2
\end{align*}
\]

If \(y = 2\):

If \( y = 2 \): \( x = \frac{4}{2} = 2 \); If \( y = -2 \): \( x = \frac{4}{-2} = -2 \)
The two numbers are 2 and 2 or -2 and -2.

Let \( x \) and \( y \) be the two numbers. The system of equations is:
\[
\begin{align*}
xy &= 10 \Rightarrow x = \frac{10}{y} \\
x^2 - y^2 &= 21
\end{align*}
\]
Solve the first equation for \( x \), substitute into the second equation and solve:
\[
\begin{align*}
\left(\frac{10}{y}\right)^2 - y^2 &= 21 \\
\frac{100}{y^2} - y^2 &= 21 \\
100 - y^4 &= 21y^2 \\
y^4 + 21y^2 - 100 &= 0 \\
(y^2 - 4)(y^2 + 25) &= 0 \\
y^2 &= 4 \quad \text{or} \quad y^2 = -25 \quad \text{(no real solution)} \\
y &= \pm 2
\end{align*}
\]
If \( y = 2 \): \( x = \frac{10}{2} = 5 \)
If \( y = -2 \): \( x = \frac{10}{-2} = -5 \)
The two numbers are 2 and 5 or -2 and -5.

Let \( x \) and \( y \) be the two numbers. The system of equations is:
\[
\begin{align*}
x - y &= xy \\
\frac{1}{x} + \frac{1}{y} &= 5
\end{align*}
\]
Solve the first equation for \( x \), substitute into the second equation and solve:
\[
\begin{align*}
x - xy &= y \\
x(1-y) &= y \\
x &= \frac{y}{1-y}
\end{align*}
\]
\[
\begin{align*}
\frac{1}{y} + \frac{1}{y} &= 5 \\
\frac{1}{1-y} + \frac{1}{y} &= 5 \\
\frac{2 - y}{y} &= 5 \\
2 - y &= 5y \\
6y &= 2 \\
y &= \frac{1}{3} \\
x &= \frac{1}{1-\frac{1}{3}} = \frac{1}{\frac{2}{3}} = \frac{1}{2}
\end{align*}

The two numbers are \( \frac{1}{2} \) and \( \frac{1}{3} \).

Let \( x \) and \( y \) be the two numbers. The system of equations is:
\[
\begin{align*}
x + y &= xy \\
\frac{1}{x} - \frac{1}{y} &= 3
\end{align*}
\]
Solve the first equation for \( x \), substitute into the second equation and solve:
\[
\begin{align*}
xy - x &= y \\
x(y-1) &= y \\
x &= \frac{y}{y-1}
\end{align*}
\]
\[
\begin{align*}
\frac{1}{y-1} - \frac{1}{y} &= 3 \\
\frac{y-1}{y} - \frac{1}{y} &= 3 \\
\frac{y-2}{y} &= 3 \\
y - 2 &= 3y \\
2y &= -2 \\
y &= -1 \\
x &= \frac{-1}{-1-1} = \frac{1}{2}
\end{align*}
\]
The two numbers are \( -1 \) and \( \frac{1}{2} \).

77. \[
\begin{align*}
\frac{a}{b} &= \frac{2}{3} \\
\end{align*}
\]
\[a + b = 10 \Rightarrow a = 10 - b\]

Solve the second equation for \(a\), substitute into the first equation and solve:
\[
\begin{align*}
10 - b &= \frac{2}{3} \\
3(10 - b) &= 2b \\
30 - 3b &= 2b \\
30 &= 5b \\
b &= 6 \Rightarrow a = 4 \\
a + b &= 10; \quad b - a = 2
\end{align*}
\]
The ratio of \(a + b\) to \(b - a\) is \(\frac{10}{2} = 5\).

78. \[
\begin{align*}
\frac{a}{b} &= \frac{4}{3} \\
\end{align*}
\]
\[a + b = 14 \Rightarrow a = 14 - b\]

Solve the second equation for \(a\), substitute into the first equation and solve:
\[
\begin{align*}
14 - b &= \frac{4}{3} \\
3(14 - b) &= 4b \\
42 - 3b &= 4b \\
42 &= 7b \\
b &= 6 \Rightarrow a = 8 \\
a - b &= 2; \quad a + b = 14
\end{align*}
\]
The ratio of \(a - b\) to \(a + b\) is \(\frac{2}{14} = \frac{1}{7}\).

79. Let \(x\) = the width of the rectangle.
Let \(y\) = the length of the rectangle.
\[
\begin{align*}
2x + 2y &= 16 \\
xy &= 15
\end{align*}
\]

Solve the first equation for \(y\), substitute into the second equation and solve.
\[
\begin{align*}
2x + 2y &= 16 \\
2y &= 16 - 2x \\
y &= 8 - x \\
x(8 - x) &= 15 \\
8x - x^2 &= 15 \\
x^2 - 8x + 15 &= 0 \\
(x - 5)(x - 3) &= 0 \\
x &= 5 \quad \text{or} \quad x = 3
\end{align*}
\]
The dimensions of the rectangle are 3 inches by 5 inches.

80. Let \(2x\) = the side of the first square.
Let \(3x\) = the side of the second square.
\[
\begin{align*}
(2x)^2 + (3x)^2 &= 52 \\
4x^2 + 9x^2 &= 52 \\
13x^2 &= 52 \\
x^2 &= 4 \\
x &= \pm 2
\end{align*}
\]
Note that we must have \(x > 0\).
The sides of the first square are \((2)(2) = 4\) feet and the sides of the second square are \((3)(2) = 6\) feet.

81. Let \(x\) = the radius of the first circle.
Let \(y\) = the radius of the second circle.
\[
\begin{align*}
2\pi x + 2\pi y &= 12\pi \\
\pi x^2 + \pi y^2 &= 20\pi
\end{align*}
\]
Solve the first equation for \(y\), substitute into the second equation and solve:
\[
\begin{align*}
2\pi x + 2\pi y &= 12\pi \\
x + y &= 6 \\
y &= 6 - x \\
\pi x^2 + \pi y^2 &= 20\pi \\
x^2 + y^2 &= 20 \\
x^2 + (6 - x)^2 &= 20 \\
x^2 + 36 - 12x + x^2 &= 20 \\
2x^2 - 12x + 16 &= 0 \\
x^2 - 6x + 8 &= 0 \Rightarrow (x - 4)(x - 2) = 0 \\
x &= 4 \quad \text{or} \quad x = 2 \\
y &= 2 \quad y = 4
\end{align*}
\]
The radii of the circles are 2 centimeters and 4 centimeters.

82. Let \(x\) = the length of each of the two equal sides in the isosceles triangle.
Let \(y\) = the length of the base.
The perimeter of the triangle: \(x + x + y = 18\)
Since the altitude to the base \(y\) is 3, the Pythagorean theorem produces another equation.
\[
\begin{align*}
\left(\frac{y}{2}\right)^2 + 3^2 &= x^2 \\
\Rightarrow \frac{y^2}{4} + 9 &= x^2
\end{align*}
\]
Solve the system of equations:
\[
\begin{align*}
2x + y &= 18 \quad \Rightarrow \quad y = 18 - 2x \\
\frac{y^2}{4} + 9 &= x^2
\end{align*}
\]
Solve the first equation for \( y \), substitute into the second equation and solve.

\[
\frac{(18-2x)^2}{4} + 9 = x^2
\]
\[
\frac{324 - 72x + 4x^2}{4} + 9 = x^2
\]
\[
81 - 18x + x^2 + 9 = x^2
\]
\[-18x = -90
\]
\[
x = 5 \quad \Rightarrow \quad y = 18 - 2(5) = 8
\]
The base of the triangle is 8 centimeters.

83. The tortoise takes \( 9 + 3 = 12 \) minutes or 0.2 hour longer to complete the race than the hare.

Let \( r \) = the rate of the hare.

Let \( t \) = the time for the hare to complete the race. Then \( t + 0.2 \) = the time for the tortoise and \( r - 0.5 \) = the rate for the tortoise. Since the length of the race is 21 meters, the distance equations are:

\[
\begin{align*}
rt &= 21 \quad \Rightarrow \quad r = \frac{21}{t} \\
(r-0.5)(t+0.2) &= 21
\end{align*}
\]

Solve the first equation for \( r \), substitute into the second equation and solve:

\[
\left( \frac{21}{t} - 0.5 \right)(t+0.2) = 21
\]
\[
21 + \frac{4.2}{t} - 0.5t - 0.1 = 21
\]
\[
10t \left( 21 + \frac{4.2}{t} - 0.5t - 0.1 \right) = 10t \cdot (21)
\]
\[
210t + 42 - 5t^2 - t = 210t
\]
\[
5t^2 + t - 42 = 0
\]
\[
(5t-14)(t+3) = 0
\]
\[
5t - 14 = 0 \quad \text{or} \quad t + 3 = 0
\]
\[
t = 14/5 = 2.8
\]
\[
t = -3 \quad \text{makes no sense, since time cannot be negative.}
\]

Solve for \( r \):

\[
r = \frac{21}{2.8} = 7.5
\]
The average speed of the hare is 7.5 meters per hour, and the average speed for the tortoise is 7 meters per hour.

84. Let \( v_1, v_2, v_3 \) = the speeds of runners 1, 2, 3.

Let \( t_1, t_2, t_3 \) = the times of runners 1, 2, 3.

Then by the conditions of the problem, we have the following system:

\[
\begin{align*}
5280 &= v_1 t_1 \\
5270 &= v_2 t_1 \\
5260 &= v_3 t_1 \\
5280 &= v_2 t_2
\end{align*}
\]

Distance between the second runner and the third runner after \( t_2 \) seconds is:

\[
5280 - v_1 t_2 = 5280 - v_3 t_1 \left( \frac{v_2 t_2}{v_2 t_1} \right)
\]
\[
= 5280 - 5260 \left( \frac{5280}{5270} \right)
\]
\[
\approx 10.02
\]
The second place runner beats the third place runner by about 10.02 feet.

85. Let \( x \) = the width of the cardboard. Let \( y \) = the length of the cardboard. The width of the box will be \( x - 4 \), the length of the box will be \( y - 4 \), and the height is 2. The volume is \( V = (x-4)(y-4)(2) \).

Solve the system of equations:

\[
\begin{align*}
xy &= 216 \quad \Rightarrow \quad y = \frac{216}{x} \\
2(x-4)(y-4) &= 224
\end{align*}
\]

Solve the first equation for \( y \), substitute into the second equation and solve.

\[
(2x-8) \left( \frac{216}{x} - 4 \right) = 224
\]
\[
432 - 8x - \frac{1728}{x} + 32 = 224
\]
\[
432 - 8x^2 - 1728 + 32x = 224x
\]
\[
8x^2 - 240x + 1728 = 0
\]
\[
x^2 - 30x + 216 = 0
\]
\[
(x-12)(x-18) = 0
\]
\[
x = 12 \quad \text{or} \quad x = 18
\]
\[
x = 12 \quad \text{and} \quad x = 18
\]
The cardboard should be 12 centimeters by 18 centimeters.
86. Let \( x \) = the width of the cardboard. Let \( y \) = the length of the cardboard. The area of the cardboard is: \( xy = 216 \) 

The volume of the tube is: \( V = \pi r^2 h = 224 \) where \( h = y \) and \( 2\pi r = x \) or \( r = \frac{x}{2\pi} \).

Solve the system of equations:

\[
\begin{align*}
xy &= 216 \\
\pi \left( \frac{x}{2\pi} \right)^2 y &= 224 \\
\frac{x^2 y}{4\pi} &= 224
\end{align*}
\]

Solve the first equation for \( y \), substitute into the second equation and solve.

\[
\begin{align*}
x^2 \left( \frac{216}{x} \right) &= 224 \\
216x &= 896\pi \\
x &= \frac{896\pi}{216} \approx 13.03
\end{align*}
\]

\[
\begin{align*}
y &= \frac{216}{x} \approx \frac{(216)^2}{896\pi} \approx 16.57
\end{align*}
\]

The cardboard should be about 13.03 centimeters by 16.57 centimeters.

87. Find equations relating area and perimeter:

\[
\begin{align*}
x^2 + y^2 &= 4500 \\
3x + 3y + (x - y) &= 300
\end{align*}
\]

Solve the second equation for \( y \), substitute into the first equation and solve:

\[
4x + 2y = 300 \\
2y = 300 - 4x \\
y = 150 - 2x \\
x^2 + (150 - 2x)^2 = 4500
\]

\[
\begin{align*}
x^2 + 22,500 - 600x + 4x^2 &= 4500 \\
5x^2 - 600x + 18,000 &= 0 \\
x^2 - 120x + 3600 &= 0 \\
(x - 60)^2 &= 0 \\
x - 60 &= 0 \\
x &= 60
\end{align*}
\]

\[
\begin{align*}
y &= 150 - 2(60) = 30
\end{align*}
\]

The sides of the squares are 30 feet and 60 feet.

88. Let \( x \) = the length of a side of the square. Let \( r \) = the radius of the circle. The area of the square is \( x^2 \) and the area of the circle is \( \pi r^2 \). The perimeter of the square is \( 4x \) and the circumference of the circle is \( 2\pi r \). Find equations relating area and perimeter:

\[
\begin{align*}
x^2 + \pi r^2 &= 100 \\
4x + 2\pi r &= 60
\end{align*}
\]

Solve the second equation for \( x \), substitute into the first equation and solve:

\[
\begin{align*}
4x &= 60 - 2\pi r \\
x &= 15 - \frac{1}{2}r
\end{align*}
\]

\[
\begin{align*}
\left( 15 - \frac{1}{2} \pi r \right)^2 + \pi r^2 &= 100 \\
225 - 15\pi r + \frac{1}{4}\pi^2 r^2 + \pi r^2 &= 100 \\
\left( \frac{1}{4}\pi^2 + \pi \right) r^2 - 15\pi r + 125 &= 0
\end{align*}
\]

\[
\begin{align*}
b^2 - 4ac &= ( -15\pi )^2 - 4 \left( \frac{1}{4}\pi^2 + \pi \right)(125) \\
&= 225\pi^2 - 500 \left( \frac{1}{4}\pi^2 + \pi \right) \\
&= 100\pi^2 - 500\pi < 0
\end{align*}
\]

Since the discriminant is less than zero, it is impossible to cut the wire into two pieces whose total area equals 100 square feet.

89. Solve the system for \( l \) and \( w \):

\[
\begin{align*}
2l + 2w &= P \\
lw &= A
\end{align*}
\]

Solve the first equation for \( l \), substitute into the second equation and solve.

\[
\begin{align*}
2l &= P - 2w \\
l &= \frac{P}{2} - w \\
\left( \frac{P}{2} - w \right)w &= A \\
\frac{P}{2}w - w^2 &= A \\
w^2 - \frac{P}{2}w + A &= 0
\end{align*}
\]
Section 8.6: Systems of Nonlinear Equations

90. Solve the system for \( l \) and \( b \):
\[
\begin{aligned}
P &= b + 2l \\ h^2 + \frac{b^2}{4} &= l^2
\end{aligned}
\]
Solve the first equation for \( b \), substitute into the second equation and solve.
\[
\begin{aligned}
4h^2 + b^2 &= 4l^2 \\
4h^2 + (P - 2l)^2 &= 4l^2 \\
4h^2 + P^2 - 4Pl + 4l^2 &= 4l^2 \\
4h^2 + P^2 &= 4Pl
\end{aligned}
\]
\[
I = \frac{4h^2 + P^2}{4P}
\]
\[
b = P - \frac{4h^2 + P^2}{2P} = \frac{P^2 - 4h^2}{2P}
\]

91. Solve the equation: \( m^2 - 4(2m - 4) = 0 \)
\[
m^2 - 8m + 16 = 0 \\
(m - 4)^2 = 0 \\
m = 4
\]
Use the point-slope equation with slope 4 and the point (2, 4) to obtain the equation of the tangent line:
\[
y - 4 = 4(x - 2) \Rightarrow y - 4 = 4x - 8 \Rightarrow y = 4x - 4
\]

92. Solve the system:

x^2 + m^2x^2 + 2bmx + b^2 - 10 = 0 \\
(1 + m^2)x^2 + 2bmx + b^2 - 10 = 0
\]
Note that the tangent line passes through (1, 3). Find the relation between \( m \) and \( b \):
\[
3 = m(1) + b \Rightarrow b = 3 - m
\]
There is one solution to the quadratic if the discriminant is zero.
\[
(2bm)^2 - 4\left(m^2 + 1\right)(b^2 - 10) = 0 \\
4b^2m^2 - 4b^2m^2 + 40m^2 - 4b^2 + 40 = 0 \\
40m^2 - 4b^2 + 40 = 0
\]
Substitute for \( b \) and solve:
\[
40m^2 - 4(3 - m)^2 + 40 = 0 \\
40m^2 - 4m^2 + 24m - 36 + 40 = 0 \\
36m^2 + 24m + 4 = 0 \\
9m^2 + 6m + 1 = 0 \\
(3m + 1)^2 = 0 \\
3m = -1 \\
m = \frac{-1}{3}
\]
\[
b = 3 - m = 3 - \left(-\frac{1}{3}\right) = \frac{10}{3}
\]
The equation of the tangent line is 
\[
y = -\frac{1}{3}x + \frac{10}{3}.
\]

93. Solve the system:
\[
\begin{aligned}

x^2 + 2 = mx + b \Rightarrow x^2 - mx + 2 - b = 0
\]
Note that the tangent line passes through (1, 3). Find the relation between \( m \) and \( b \):
\[
3 = m(1) + b \Rightarrow b = 3 - m
\]
Substitute into the quadratic to eliminate \( b \):
\[
x^2 - mx + 2 - (3 - m) = 0 \Rightarrow x^2 - mx + (m - 1) = 0

Find when the discriminant equals 0:
\((m)^2 - 4(1)(2m - 4) = 0\)
\(m^2 - 8m + 16 = 0\)
\((m - 4)^2 = 0\)
\(m = 4\)
\(b = 2m + 1 = 2(4) + 1 = 9\)
The equation of the tangent line is \(y = 4x + 9\).

95. Solve the system:

\end{align*}\]
Solve the system by substitution:
\(2x^2 + 3(mx + b)^2 = 14\)
\(2x^2 + 3m^2x^2 + 6mbx + 3b^2 = 14\)
\((3m^2 + 2)x^2 + 6mbx + 3b^2 - 14 = 0\)
Note that the tangent line passes through \((1, 2)\).
Find the relation between \(m\) and \(b\):
\(2 = m(1) + b \Rightarrow b = 2 - m\)
Substitute into the quadratic to eliminate \(b\):
\((3m^2 + 2)x^2 + 6m(2 - m)x + 3(2 - m)^2 - 14 = 0\)
\((3m^2 + 2)x^2 + (12m - 6m^2)x + (3m^2 - 12m - 2) = 0\)
Find when the discriminant equals 0:
\((12m - 6m^2)^2 - 4(3m^2 + 2)(3m^2 - 12m - 2) = 0\)
\(144m^2 + 96m + 16 = 0\)
\(9m^2 + 6m + 1 = 0\)
\((3m + 1)^2 = 0\)
\(3m + 1 = 0\)
\(m = -\frac{1}{3}\)
\(b = 2 - m = 2 - \left(-\frac{1}{3}\right) = \frac{7}{3}\)
The equation of the tangent line is \(y = -\frac{1}{3}x + \frac{7}{3}\).

\(3x^2 + m^2x^2 + 2mbx + b^2 = 7\)
\((m^2 + 3)x^2 + 2mbx + b^2 - 7 = 0\)
Note that the tangent line passes through \((-1, 2)\).
Find the relation between \(m\) and \(b\):
\(2 = m(-1) + b \Rightarrow b = m + 2\)
There is one solution to the quadratic if the discriminant equals 0.
\((2bm)^2 - 4(m^2 + 3)(b^2 - 7) = 0\)
\(4b^2m^2 - 4b^2m^2 + 28m^2 - 12b^2 + 84 = 0\)
\(28m^2 - 12b^2 + 84 = 0\)
\(7m^2 - 3b^2 + 21 = 0\)
Substitute for \(b\) and solve:
\(7m^2 - 3(m^2 + 2)^2 + 21 = 0\)
\(7m^2 - 3m^2 - 12m + 21 = 0\)
\(4m^2 - 12m + 9 = 0\)
\((2m - 3)^2 = 0\)
\(2m = 3\)
\(m = \frac{3}{2}\)
\(b = m + 2 = \frac{3}{2} + 2 = \frac{7}{2}\)
The equation of the tangent line is \(y = \frac{3}{2}x + \frac{7}{2}\).

\end{align*}
\]
Find when the discriminant equals 0:
\[
\begin{align*}
(2m + 4m^2)^2 - 4(1 - m^2)(-4m^2 + 4m - 4) &= 0 \\
4m^2 - 16m^3 + 16m^4 - 16m^4 + 16m^3 - 16m + 16 &= 0 \\
4m^2 - 16m + 16 &= 0 \\
m^2 - 4m + 4 &= 0 \\
(m - 2)^2 &= 0 \\
m &= 2
\end{align*}
\]
The equation of the tangent line is \(y = 2x - 3\).

98. Solve the system:
\[
\begin{align*}
2y^2 - x^2 &= 14 \\
y &= mx + b
\end{align*}
\]
Solve the system by substitution:
\[
\begin{align*}
2(mx + b)^2 - x^2 &= 14 \\
2m^2x^2 + 4mbx + 2b^2 - x^2 &= 14 \\
(2m^2 - 1)x^2 + 4mbx + 2b^2 - 14 &= 0
\end{align*}
\]
Note that the tangent line passes through (2, 3).
Find the relation between \(m\) and \(b\):
\[
3 = m(2) + b \Rightarrow b = 3 - 2m
\]
There is one solution to the quadratic if the discriminant equals 0.
\[
\begin{align*}
(4bm)^2 - 4(2m^2 - 1)(2b^2 - 14) &= 0 \\
16b^2m^2 - 16b^2m^2 + 112m^2 + 8b^2 - 56 &= 0 \\
112m^2 + 8b^2 - 56 &= 0 \\
14m^2 + b^2 - 7 &= 0
\end{align*}
\]
Substitute for \(b\) and solve:
\[
\begin{align*}
14m^2 + (3 - 2m)^2 - 7 &= 0 \\
14m^2 + 4m^2 - 12m + 9 - 7 &= 0 \\
18m^2 - 12m + 2 &= 0 \\
2(3m - 1)^2 &= 0 \\
3m &= 1 \\
m &= \frac{1}{3}
\end{align*}
\]
\[
\begin{align*}
b &= 3 - 2m = 3 - 2\left(\frac{1}{3}\right) = \frac{7}{3}
\end{align*}
\]
The equation of the tangent line is \(y = \frac{1}{3}x + \frac{7}{3}\).

99. Solve for \(r_1\) and \(r_2\):
\[
\begin{align*}
\begin{cases}
r_1 + r_2 = -\frac{b}{a} \\
r_1 r_2 = \frac{c}{a}
\end{cases}
\end{align*}
\]
Substitute and solve:
\[
\begin{align*}
r_1 &= -r_2 - \frac{b}{a} \\
r_2 &= \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}
\end{align*}
\]
\[
\begin{align*}
r_1 &= -r_2 - \frac{b}{a} \\
r_2 &= \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \\
&= -\left(\frac{-b \pm \sqrt{b^2 - 4ac}}{2a}\right) - \frac{b}{a} \\
&= \frac{b \mp \sqrt{b^2 - 4ac}}{2a} - \frac{2b}{2a} \\
&= \frac{b \mp \sqrt{b^2 - 4ac}}{2a}
\end{align*}
\]
The solutions are:
\[
\begin{align*}
r_1 &= \frac{-b + \sqrt{b^2 - 4ac}}{2a} \quad \text{and} \quad r_2 = \frac{-b - \sqrt{b^2 - 4ac}}{2a}
\end{align*}
\]
Chapter 8: Systems of Equations and Inequalities

100. Consider the circle with equation
\[(x - h)^2 + (y - k)^2 = r^2\]
and the third degree polynomial with equation \[y = ax^3 + bx^2 + cx + d\].
Substituting the second equation into the first equation yields
\[(x - h)^2 + (ax^3 + bx^2 + cx + d - k)^2 = r^2\].
In order to find the roots for this equation we can expand the terms on the left hand side of the equation. Notice that \((x - h)^2\) yields a 2nd degree polynomial, and \((ax^3 + bx^2 + cx + d - k)^2\) yields a 6th degree polynomial. Therefore, we need to find the roots of a 6th degree equation, and the Fundamental Theorem of Algebra states that there will be at most 6 real roots. Thus, the circle and the 3rd degree polynomial will intersect at most 6 times. Now consider the circle with equation
\[(x - h)^2 + (y - k)^2 = r^2\]
and the polynomial of degree \(n\) with equation \[y = a_0 + a_1x + a_2x^2 + a_3x^3 + \ldots + a_nx^n\].
Substituting the first equation into the first equation yields
\[(x - h)^2 + (a_0 + a_1x + a_2x^2 + a_3x^3 + \ldots + a_nx^n - k)^2 = r^2\].
In order to find the roots for this equation we can expand the terms on the left hand side of the equation. Notice that \((x - h)^2\) yields a 2nd degree polynomial, and \((a_0 + a_1x + a_2x^2 + a_3x^3 + \ldots + a_nx^n - k)^2\) yields a polynomial of degree 2n.
Therefore, we need to find the roots of an equation of degree 2n, and the Fundamental Theorem of Algebra states that there will be at most 2n real roots. Thus, the circle and the \(n^{th}\) degree polynomial will intersect at most 2n times.

101. Since the area of the square piece of sheet metal is 100 square feet, the sheet’s dimensions are 10 feet by 10 feet. Let \(x\) = the length of the cut. The dimensions of the box are: length = 10 − 2x; width = 10 − 2x; height = x. Note that each of these expressions must be positive. So we must have \(x > 0\) and \(10 - 2x > 0 \Rightarrow x < 5\), that is, \(0 < x < 5\). So the volume of the box is given by
\[V = (\text{length}) \cdot (\text{width}) \cdot (\text{height}) = (10 - 2x)(10 - 2x)(x) = (10 - 2x)^2 x\]
a. In order to get a volume equal to 9 cubic feet, we solve \((10 - 2x)^2 x = 9\).
\[(10 - 2x)^2 (x) = 9\]
\[(100 - 40x + 4x^2) x = 9\]
\[100x - 40x^2 + 4x^3 = 9\]
So we need to solve the equation
\[4x^3 - 40x^2 + 100x - 9 = 0\].
Graphing \(y_1 = 4x^3 - 40x^2 + 100x - 9\) on a calculator yields the graph

The graph indicates that there are three real zeros on the interval \([0, 6]\). Using the ZERO feature of a graphing calculator, we find that the three roots shown occur at \(x \approx 0.093\), \(x \approx 4.274\) and \(x \approx 5.632\). But we’ve already noted that we must have \(0 < x < 5\), so the only practical values for the sides of the square base are \(x \approx 0.093\) feet and \(x \approx 4.274\) feet.

24. Let $x$ = the number of hours that machine 1 is operated, and let $y$ = the number of hours that machine 2 is operated. The total cost is:

$C = 50x + 30y$. Cost is to be minimized, so this is the objective function.

The constraints are:

- $x \geq 0$, $y \geq 0$ A positive number of hours must be used.
- $x \leq 10$ Time used on machine 1.
- $y \leq 10$ Time used on machine 2.
- $60x + 40y \geq 240$ 8-inch pliers to be produced.
- $70x + 20y \geq 140$ 6-inch pliers to be produced.

Graph the constraints.

To find the intersection of $60x + 40y = 240$ and $70x + 20y = 140$, solve the system:

$$
\begin{align*}
60x + 40y &= 240 \\
70x + 20y &= 140
\end{align*}
$$

Divide the first equation by $-2$ and add the result to the second equation:

$$
\begin{align*}
-30x - 20y &= -120 \\
70x + 20y &= 140
\end{align*}
$$

Solve:

$$x = \frac{20}{40} = \frac{1}{2}$$

Substitute and solve:

$$
\begin{align*}
60\left(\frac{1}{2}\right) + 40y &= 240 \\
30 + 40y &= 240 \\
40y &= 210 \\
y &= \frac{210}{40} = \frac{21}{4} = \frac{51}{4}
\end{align*}
$$

The point of intersection is $\left(\frac{1}{2}, \frac{51}{4}\right)$.

Chapter 8: Systems of Equations and Inequalities

The corner points are (8, 96), (8, 120), and (10, 120). Evaluate the objective function:

<table>
<thead>
<tr>
<th>Vertex</th>
<th>Value of $R = Fx + Cy$</th>

<tbody>
<tr>
<td>(8, 96)</td>
<td>$R = 8F + 96C$</td>

<td>$R = 8F + 120C$</td>
</tr>
<tr>
<td>(10, 120)</td>
<td>$R = 10F + 120C$</td>
</tr>
</tbody>
</table>

Since $C > 0$, $120C > 96C$, so $8F + 120C > 8F + 96C$.
Since $F > 0$, $10F > 8F$, so $10F + 120C > 8F + 120C$.
Thus, the maximum revenue occurs when the aircraft is configured with 10 first class seats and 120 coach seats.

b. \[ \frac{x}{y} \leq \frac{1}{8} \]
The constraints are:
\[ 8 \leq x \leq 16 \]
\[ 80 \leq y \leq 120 \]
\[ 8x \leq y \]
Graph the constraints.

The corner points are (8, 80), (8, 120), (15, 120), and (10, 80).
Evaluate the objective function:

<table>

<td>$R = 15F + 120C$</td>
</tr>
<tr>
<td>(10, 80)</td>
<td>$R = 10F + 80C$</td>

Since $F > 0$ and $C > 0$, $120C > 96C$, the maximum value of $R$ occurs at (15, 120).
The maximum revenue occurs when the aircraft is configured with 15 first class seats and 120 coach seats.

x - 2y - 4 &= 0 \\
3x + 2y - 4 &= 0
\end{align*}
\]

\begin{align*}
3(2y + 4) + 2y - 4 &= 0 \\
6y + 12 + 2y - 4 &= 0 \\
8y &= -8 \\

\begin{align*}
2(3y - 5) + 3y - 5 &= 0 \\
6y - 10 + 3y - 5 &= 0 \\
9y &= 15 \\
y &= \frac{5}{3}
\end{align*}
\]
\[
x = 3\left(\frac{5}{3}\right) - 5 = 0
\]
The solution is \( x = 0, y = \frac{5}{3} \) or \( \left(0, \frac{5}{3}\right) \).

7. \[
\begin{align*}
y &= 2x - 5 \\

\begin{align*}
\begin{cases}
  2x + 3y - 13 &= 0 \\
  3x - 2y &= 0
\end{cases}
\end{align*}
\]
Multiply each side of the first equation by 2 and each side of the second equation by 3, and add to eliminate \(y\):
\[
\begin{align*}
\begin{cases}
  4x + 6y - 26 &= 0 \\
  9x - 6y &= 0
\end{cases}
\end{align*}
\]
Substitute and solve for \(y\):
\[
\begin{align*}
  3(2) - 2y &= 0 \\
  -2y &= -6 \\
  y &= 3
\end{align*}
\]
The solution is \(x = 2, \ y = 3\) or \((2, 3)\).

\begin{align*}
\begin{cases}
  4x + 5y &= 21 \\
  5x + 6y &= 42
\end{cases}
\end{align*}
\]
Multiply each side of the first equation by 5 and each side of the second equation by -4 and add to eliminate \(x\):
\[
\begin{align*}
\begin{cases}
  20x + 25y &= 105 \\
  -20x - 24y &= -168
\end{cases}
\end{align*}
\]
Substitute and solve for \(x\):
\[
\begin{align*}
  4x + 5(-63) &= 21 \\
  4x - 315 &= 21 \\
  4x &= 336 \\
  x &= 84
\end{align*}
\]
The solution is \(x = 84, \ y = -63\) or \((84, -63)\).

13. \[
\begin{align*}
\begin{cases}
  3x - 2y &= 8 \\
  x - \frac{2}{3}y &= 12
\end{cases}
\end{align*}
\]
Multiply each side of the second equation by -3 and add to eliminate \(x\):
\[
\begin{align*}
\begin{cases}
  3x - 2y &= 8 \\
  -3x + 2y &= -36
\end{cases}
\end{align*}
\]
\[
0 = -28
\]
There is no solution to the system. The system of equations is inconsistent.

14. \[
\begin{align*}
\begin{cases}
  2x + 5y &= 10 \\
  4x + 10y &= 20
\end{cases}
\end{align*}
\]
Multiply each side of the first equation by -2 and add to eliminate \(x\):
\[
\begin{align*}
\begin{cases}
  -4x - 10y &= -20 \\
  4x + 10y &= 20
\end{cases}
\end{align*}
\]
\[
0 = 0
\]
The system is dependent.
\[
\begin{align*}
  2x + 5y &= 10 \\
  5y &= -2x + 10 \\
  y &= \frac{2}{5}x + 2
\end{align*}
\]
The solution is \(y = \frac{2}{5}x + 2, \ x\) is any real number or \((x, y) = \left\{ \left( x, \frac{2}{5}x + 2 \right) | x \text{ is any real number} \right\}\).

15. \[
\begin{align*}
\begin{cases}
  x + 2y - z &= 6 \\
  2x - y + 3z &= -13 \\
  3x - 2y + 3z &= -16
\end{cases}
\end{align*}
\]
Multiply each side of the first equation by -2 and add to the second equation to eliminate \(x\):
\[
\begin{align*}
\begin{cases}
  -2x - 4y + 2z &= -12 \\
  2x - y + 3z &= -13 \\
  -5y + 5z &= -25
\end{cases}
\end{align*}
\]
\[
y - z = 5
\]
Multiply each side of the first equation by -3 and add to the third equation to eliminate \(x\):
\[
\begin{align*}
\begin{cases}
  -3x - 6y + 3z &= -18 \\
  3x - 2y + 3z &= -16 \\
  -8y + 6z &= -34
\end{cases}
\end{align*}
\]
Multiply each side of the first result by 8 and add to the second result to eliminate \(y\):
8y – 8z = 40
–8y + 6z = –34
\[\begin{align*}
\text{Subtracting the second equation from the first:} \\
\quad -2z &= 6 \\
\quad z &= -3
\end{align*}\]

Substituting and solving for the other variables:
y – (–3) = 5 \quad x + 2(2) – (–3) = 6
y = 2 \quad x + 4 + 3 = 6
x = –1

The solution is \(x = –1, y = 2, z = –3\) or \((-1, 2, –3)\).

\[\begin{align*}
x + 5y – z &= 2 \\
2x + y + z &= 7 \\
x – y + 2z &= 11
\end{align*}\]

Add the first equation and the second equation to eliminate \(z\):
\[\begin{align*}
x + 5y &– z = 2 \\
2x + y &+ z = 7 \\
3x + 6y &= 9
\end{align*}\]
\[-x – 2y = -3\]

Multiply each side of the first equation by 2 and add to the third equation to eliminate \(z\):
\[\begin{align*}
x + 10y &– 2z = 4 \\
x – y + 2z &= 11 \\
3x + 9y &= 15
\end{align*}\]
\[x + 3y = 5\]

Add the two results to eliminate \(x\):
\[-x – 2y = -3 \\
x + 3y &= 5
\]
\[y = 2\]

Substituting and solving for the other variables:
x + 3(2) = 5 \quad 2(–1) + 2 + z = 7
x + 6 = 5 \quad -2 + 2 + z = 7
x = –1 \quad z = 7

The solution is \(x = –1, y = 2, z = 7\) or \((-1, 2, 7)\).

\[\begin{align*}
x + 2y – 4z &= 27 \\
5x &– 6y – 2z = –3
\end{align*}\]

Multiply the first equation by \(-1\) and the second equation by 2, and then add to eliminate \(x\):
\[-2x + 4y – z = 15 \\
2x &+ 4y – 8z = 54
\]
\[8y – 9z = 69\]

Multiply the second equation by \(-5\) and add to the third equation to eliminate \(x\):
\[-5x – 10y + 20z = –135 \\
5x &– 6y – 2z = –3
\]
\[-16y + 18z = –138\]

Multiply both sides of the first result by 2 and add to the second result to eliminate \(y\):
\[-16y + 18z = –138 \\
0 &= 0\]

The system is dependent.

\[-16y + 18z = –138 \quad 18z + 138 = 16y \]
\[y = \frac{9}{8}z + \frac{69}{8}\]

Substituting into the second equation and solving for \(x\):
\[x + 2\left(\frac{9}{8}z + \frac{69}{8}\right) – 4z = 27\]
\[x + \frac{9}{4}z + \frac{69}{4} – 4z = 27\]
\[x = \frac{7}{4}z + \frac{39}{4}\]

The solution is \(x = \frac{7}{4}z + \frac{39}{4}, y = \frac{9}{8}z + \frac{69}{8}, z\) is any real number or \((x, y, z) | x = \frac{7}{4}z + \frac{39}{4}, y = \frac{9}{8}z + \frac{69}{8}, z\) is any real number \(\} \).

\[\begin{align*}
x – 4y + 3z &= 15 \\
-3x + y &– 5z = –5
\end{align*}\]

Multiply the first equation by \(3\) and then add the second equation to eliminate \(x\):
\[3x – 12y + 9z = 45 \\
-3x + y &– 5z = –5
\]
\[-11y + 4z = 40\]

Multiply the first equation by \(7\) and add to the third equation to eliminate \(x\):
\[7x – 28y + 21z = 105 \\
-7x &– 5y – 9z = 10
\]
\[-33y + 12z = 115 \]
\[-11y + 4z = \frac{115}{3}\]
Multiply the first result by $-1$ and adding it to the second result:
\[
\begin{align*}
11y - 4z &= -40 \\
-11y + 4z &= \frac{115}{3}
\end{align*}
\]
\[
0 = -\frac{5}{3}
\]

Let \(x = 2\), then
\[
2^2 = A(2 + 1)(2^2 + 1) + B(2 - 1)(2^2 + 1) + (C + D)(2 - 1)(2 + 1)
\]
\[4 = 15A + 5B + 6C + 3D\]
\[4 = 15\left(\frac{1}{4}\right) + 5\left(-\frac{1}{4}\right) + 6C + 3\left(\frac{1}{2}\right)\]
\[6C = 4 - \frac{15}{4} + \frac{5}{4} - \frac{3}{2}\]
\[6C = 0\]
\(C = 0\)
\[
\frac{x^2}{(x^2 + 1)(x^2 - 1)} = \frac{1}{4} + \frac{1}{4} + \frac{1}{2}
\]
68. Find the partial fraction decomposition:
\[
\frac{4}{(x^2 + 4)(x^2 - 1)} = \frac{A}{x - 1} + \frac{B}{x - 1} + \frac{C}{(x + 1)} + \frac{D}{x^2 + 4}
\]
Multiply both sides by \((x^2 + 4)(x - 1)(x + 1)\).

\[
4 = A(x^2 + 4) + B(x - 1)(x^2 + 4) + Cx + D
\]

Let \(x = 1\), then
\[
4 = A(1 + 1) + B(1 - 1)(1^2 + 4) + (C + D)(1 - 1)(1 + 1)
\]
\[
A = \frac{4}{10} = \frac{2}{5}
\]

Let \(x = 0\), then
\[
4 = A(0 + 1)(1^2 + 4) + B(0 - 1)(0^2 + 4) + (C(0) + D)(0 - 1)(0 + 1)
\]
\[
4 = 4A - 4B - D
\]
\[
4 = 4\left(\frac{2}{5}\right) - 4\left(-\frac{2}{5}\right) - D
\]
\[
D = \frac{4}{5}
\]

Let \(x = 2\), then
\[
4 = A(2 + 1)(2^2 + 4) + B(2 - 1)(2^2 + 4) + C(2 + D)(2 - 1)(2 + 1)
\]
\[
4 = 24A + 8B + 6C + 3D
\]
\[
4 = 24\left(\frac{2}{5}\right) + 8\left(-\frac{2}{5}\right) + 6C + 3\left(\frac{4}{5}\right)
\]
\[
C = 0

If \(y = \sqrt{2}\):
\[

\[
\begin{align*}
-4x - 10y &= -10 \\
4x + 10y &= A
\end{align*}
\]
\[0 = A - 10\]
If there are to be infinitely many solutions, the result of elimination should be \(0 = 0\). Therefore, \(A - 10 = 0\) or \(A = 10\).

98. \[
\begin{align*}
2x + 5y &= 5 \\
4x + 10y &= A
\end{align*}
\]
Multiply each side of the first equation by \(-2\) and eliminate \(x\):
\[
\begin{align*}
-4x - 10y &= -10 \\
4x + 10y &= A
\end{align*}
\]
\[0 = A - 10\]
If the system is to be inconsistent, the result of elimination should be \(0 = \text{any number except 0}\). Therefore, \(A - 10 \neq 0\) or \(A \neq 10\).

99. \(y = ax^2 + bx + c\)
At \((0, 1)\) the equation becomes:
\[1 = a(0)^2 + b(0) + c\]
\[c = 1\]
At \((1, 0)\) the equation becomes:
\[0 = a(1)^2 + b(1) + c\]
\[0 = a + b + c\]
\[a + b + c = 0\]
At \((-2, 1)\) the equation becomes:
\[1 = a(-2)^2 + b(-2) + c\]
\[1 = 4a - 2b + c\]
\[4a - 2b + c = 1\]
The system of equations is:
\[
\begin{align*}
a + b + c &= 0 \\
4a - 2b + c &= 1 \\
c &= 1
\end{align*}
\]
Substitute \(c = 1\) into the first and second equations and simplify:
\[
\begin{align*}
a + b + 1 &= 0 \\
4a - 2b + 1 &= 1
\end{align*}
\]
\[a + b = -1 \\
4a - 2b = 0 \\
a = -b - 1\]
Solve the first equation for $a$, substitute into the second equation and solve:

$$4(-b - 1) - 2b = 0$$
$$-4b - 4 - 2b = 0$$
$$-6b = 4$$
$$b = -\frac{2}{3}$$
$$a = \frac{2}{3} - 1 = -\frac{1}{3}$$

The quadratic function is $y = -\frac{1}{3}x^2 - \frac{2}{3}x + 1$.

100. $x^2 + y^2 + Dx + Ey + F = 0$

At $(0, 1)$ the equation becomes:

$$0^2 + 1^2 + D(0) + E(1) + F = 0$$
$$E + F = -1$$

At $(1, 0)$ the equation becomes:

$$1^2 + 0^2 + D(1) + E(0) + F = 0$$
$$D + F = -1$$

At $(-2, 1)$ the equation becomes:

$$(-2)^2 + 1^2 + D(-2) + E(1) + F = 0$$
$$-2D + E + F = -5$$

The system of equations is:

$$E + F = -1$$
$$D + F = -1$$
$$-2D + E + F = -5$$

Substitute $E + F = -1$ into the third equation and solve for $D$:

$$-2D + (-1) = -5$$
$$-2D = -4$$
$$D = 2$$

Substitute and solve:

$$2 + F = -1$$  $E + (-3) = -1$
$$F = -3$$  $E = 2$

The equation of the circle is $x^2 + y^2 + 2x + 2y - 3 = 0$.

101. Let $x$ = the number of pounds of coffee that costs $6.00 per pound, and let $y$ = the number of pounds of coffee that costs $9.00 per pound. Then $x + y = 100$ represents the total amount of coffee in the blend. The value of the blend will be represented by the equation: $6x + 9y = 6.90(100)$. Solve the system of equations:

$$\begin{cases}
    x + y = 100 \\
    6x + 9y = 690
\end{cases}$$

Solve the first equation for $y$: $y = 100 - x$.

Solve by substitution:

$$6x + 9(100 - x) = 690$$
$$6x + 900 - 9x = 690$$
$$-3x = -210$$
$$x = 70$$
$$y = 100 - 70 = 30$$

The blend is made up of 70 pounds of the $6.00-per-pound coffee and 30 pounds of the $9.00-per-pound coffee.

102. Let $x$ = the number of acres of corn, and let $y$ = the number of acres of soybeans. Then $x + y = 1000$ represents the total acreage on the farm. The total cost will be represented by the equation: $65x + 45y = 54,325$. Solve the system of equations:

$$\begin{cases}
    x + y = 1000 \\
    65x + 45y = 54,325
\end{cases}$$

Solve the first equation for $y$: $y = 1000 - x$.

Solve by substitution:

$$65x + 45(1000 - x) = 54,325$$
$$65x + 45,000 - 45x = 54,325$$
$$20x = 9325$$
$$x = 466.25$$
$$y = 1000 - 466.25 = 533.75$$

Corn should be planted on 466.25 acres and soybeans should be planted on 533.75 acres.
Chapter 8: Systems of Equations and Inequalities

103. Let \( x \) = the number of small boxes, let \( y \) = the number of medium boxes, and let \( z \) = the number of large boxes.

Oatmeal raisin equation: \( x + 2y + 2z = 15 \)
Chocolate chip equation: \( x + y + 2z = 10 \)
Shortbread equation: \( y + 3z = 11 \)

\[
\begin{align*}
x + 2y + 2z &= 15 \\
x + y + 2z &= 10 \\
y + 3z &= 11
\end{align*}
\]

Multiply each side of the second equation by \(-1\) and add to the first equation to eliminate \( x \):
\[
\begin{align*}
x + 2y + 2z &= 15 \\
-x - y - 2z &= -10 \\
y + 3z &= 11
\end{align*}
\]

Substituting and solving for the other variables:
\[
\begin{align*}
5 + 3z &= 11 \\
x + 5 + 2(2) &= 10 \\
3z &= 6 \\
x + 9 &= 10 \\
2z &= -2 \\
x &= 1 \\
z &= 2
\end{align*}
\]

Thus, 1 small box, 5 medium boxes, and 2 large boxes of cookies should be purchased.

104. a. Let \( x \) = the number of lower-priced packages, and let \( y \) = the number of quality packages.

Peanut inequality: \( 8x + 6y \leq 120(16) \)
Cashew inequality: \( 4x + 6y \leq 72(16) \)

The system of inequalities is:
\[
\begin{align*}
x &\geq 0 \\
y &\geq 0 \\
4x + 3y &\leq 960 \\
2x + 3y &\leq 576
\end{align*}
\]

b. Graphing:

To find the intersection of \( 2x + 3y = 576 \) and \( 4x + 3y = 960 \), solve the system:
\[
\begin{align*}
4x + 3y &= 960 \\
2x + 3y &= 576
\end{align*}
\]

Subtract the second equation from the first:
\[
-2x - 3y = 576 \\
2x = 384 \\
x = 192
\]

Substitute and solve:
\[
\begin{align*}
2(192) + 3y &= 576 \\
3y &= 192 \\
y &= 64
\end{align*}
\]

The corner points are \((0, 0), (0, 192), (240, 0), \) and \((192, 64)\).

105. Let \( x \) = the speed of the boat in still water, and let \( y \) = the speed of the river current. The distance from Chiritza to the Flotel Orellana is 100 kilometers.

\[
\begin{array}{ccc}
\text{Rate} & \text{Time} & \text{Distance} \\
\hline
\text{trip downstream} & x + y & 5/2 & 100 \\
\text{trip downstream} & x - y & 3 & 100
\end{array}
\]

The system of equations is:
\[
\begin{align*}
\frac{5}{2}(x + y) &= 100 \\
3(x - y) &= 100
\end{align*}
\]

Multiply both sides of the first equation by 6, multiply both sides of the second equation by 5, and add the results.
\[
\begin{align*}
15x + 15y &= 600 \\
15x - 15y &= 500
\end{align*}
\]

\[
\begin{align*}
30x &= 1100 \\
x &= \frac{1100}{30} = \frac{110}{3} \\
3 \left( \frac{110}{3} \right) - 3y &= 100 \\
110 - 3y &= 100 \\
10 &= 3y \\
y &= \frac{10}{3}
\end{align*}
\]

The speed of the boat is \( \frac{110}{3} \approx 36.67 \) km/hr; the speed of the current is \( \frac{10}{3} \approx 3.33 \) km/hr.
106. Let \( x \) = the speed of the jet stream, and let \( d \) = the distance from Chicago to Ft. Lauderdale. The jet stream flows from Chicago to Ft. Lauderdale because the time is shorter in that direction.

<table>
<thead>
<tr>
<th>Rate</th>
<th>Time</th>
<th>Distance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chicago to Ft. Lauderdale</td>
<td>( 475 + x )</td>
<td>( 5/2 )</td>
</tr>
<tr>
<td>Ft. Lauderdale to Chicago</td>
<td>( 475 - x )</td>
<td>( 17/6 )</td>
</tr>
</tbody>
</table>

The system of equations is:

\[
\begin{align*}
(475 + y)(5/2) &= d \\
(475 - y)(17/6) &= d
\end{align*}
\]

Simplifying the system, we obtain:

\[
\begin{align*}
2d - 5x &= 2375 \\
6d + 17x &= 8075
\end{align*}
\]

Multiply the first equation by \(-3\) and add the result to the second equation:

\[
\begin{align*}
-6d + 15x &= -7125 \\
6d + 17x &= 8075
\end{align*}
\]

\[
32x = 950
\]

\[
x = \frac{950}{32} = \frac{475}{16}
\]

The speed of the jet stream is approximately \( 475/16 \approx 29.69 \) miles per hour.

107. Let \( x \) = the number of hours for Bruce to do the job alone, let \( y \) = the number of hours for Bryce to do the job alone, and let \( z \) = the number of hours for Marty to do the job alone.

Then \( 1/x \) represents the fraction of the job that Bruce does in one hour.

\( 1/y \) represents the fraction of the job that Bryce does in one hour.

\( 1/z \) represents the fraction of the job that Marty does in one hour.

The equation representing Bruce and Bryce working together is:

\[
\frac{1}{x} + \frac{1}{y} = \frac{1}{4/3} = \frac{3}{4} = 0.75
\]

The equation representing Bryce and Marty working together is:

\[
\frac{1}{y} + \frac{1}{z} = \frac{1}{8/5} = \frac{5}{6} = 0.625
\]

The equation representing Bruce and Marty working together is:

\[
\frac{1}{x} + \frac{1}{z} = \frac{1}{8/3} = \frac{3}{8} = 0.375
\]

Solve the system of equations:

\[
\begin{align*}
x^{-1} + y^{-1} &= 0.75 \\
y^{-1} + z^{-1} &= 0.625 \\
x^{-1} + z^{-1} &= 0.375
\end{align*}
\]

Let \( u = x^{-1} \), \( v = y^{-1} \), \( w = z^{-1} \)

\[
\begin{align*}
u + v &= 0.75 \\
v + w &= 0.625 \\
u + w &= 0.375
\end{align*}
\]

Solve the first equation for \( u \): \( u = 0.75 - v \)

Solve the second equation for \( w \): \( w = 0.625 - v \)

Substitute into the third equation and solve:

\[
(0.75 - v) + (0.625 - v) = 0.375
\]

\[
-2v = -1
\]

\[
v = 0.5
\]

\[
u = 0.75 - 0.5 = 0.25
\]

\[
w = 0.625 - 0.5 = 0.125
\]

Solve for \( x, y, \) and \( z \): \( x = 4 \), \( y = 2 \), \( z = 8 \) (reciprocals)

Bruce can do the job in 4 hours, Bryce in 2 hours, and Marty in 8 hours.

108. Let \( x \) = the number of dancing girls produced, and let \( y \) = the number of mermaids produced.

The total profit is: \( P = 25x + 30y \) . Profit is to be maximized, so this is the objective function. The constraints are:

\[
x \geq 0,\ y \geq 0
\]

A non-negative number of figurines must be produced.

\[
3x + 3y \leq 90
\]

90 hours are available for molding.

\[
6x + 4y \leq 120
\]

120 hours are available for painting.

\[
2x + 3y \leq 60
\]

60 hours are available for glazing.

Graph the constraints.
To find the intersection of $6x + 4y = 120$ and $2x + 3y = 60$, solve the system:

\[
\begin{align*}
6x + 4y &= 120 \\
2x + 3y &= 60
\end{align*}
\]

Multiply the second equation by 3, and subtract from the first equation:

\[
\begin{align*}
6x + 4y &= 120 \\
6x - 9y &= -180 \\
-5y &= -60 \\
y &= 12
\end{align*}
\]

Substitute and solve:

\[
\begin{align*}
x + 3(12) &= 60 \\
x &= 24 \\
x &= 12
\end{align*}
\]

The point of intersection is (12, 12).

The corner points are (0, 0), (0, 20), (20, 0), (12, 12).

Evaluate the objective function:

\[
\begin{align*}
\text{Vertex} & \quad \text{Value of } P = 25x + 30y \\
(0, 0) & \quad P = 25(0) + 30(0) = 0 \\
(0, 20) & \quad P = 25(0) + 30(20) = 600 \\
(20, 0) & \quad P = 25(20) + 30(0) = 500 \\
(12, 12) & \quad P = 25(12) + 30(12) = 660
\end{align*}
\]

The maximum profit is $660, when 12 dancing girl and 12 mermaid figurines are produced each day. To determine the excess, evaluate each constraint at $x = 12$ and $y = 12$:

Molding: $3x + 3y = 3(12) + 3(12) = 36 + 36 = 72$

Painting: $6x + 4y = 6(12) + 4(12) = 72 + 48 = 120$

Glazing: $2x + 3y = 2(12) + 3(12) = 24 + 36 = 60$

Painting and glazing are at their capacity.

Molding has 18 more hours available, since only 72 of the 90 hours are used.

109. Let $x$ be the number of gasoline engines produced each week, and let $y$ be the number of diesel engines produced each week. The total cost is:

\[C = 450x + 550y\]

Cost is to be minimized; thus, this is the objective function. The constraints are:

\[
\begin{align*}
20 & \leq x \leq 60 \\
15 & \leq y \leq 40 \\
x + y & \geq 50
\end{align*}
\]

Graph the constraints.

The corner points are (20, 30), (20, 40), (35, 15), (60, 15), (60, 40)

Evaluate the objective function:

\[
\begin{align*}
\text{Vertex} & \quad \text{Value of } C = 450x + 550y \\
(20, 30) & \quad C = 450(20) + 550(30) = 25,500 \\
(20, 40) & \quad C = 450(35) + 550(40) = 31,000 \\
(35, 15) & \quad C = 450(35) + 550(15) = 24,000 \\
(60, 15) & \quad C = 450(60) + 550(15) = 35,250 \\
(60, 40) & \quad C = 450(60) + 550(40) = 49,000
\end{align*}
\]

The minimum cost is $24,000, when 35 gasoline engines and 15 diesel engines are produced. The excess capacity is 15 gasoline engines, since only 20 gasoline engines had to be delivered.

110. Answers will vary.
Chapter 8 Test

27

\[ y = 2x - 7 \]
\[ y = 2(3) - 7 = 6 - 7 = -1 \]
The solution of the system is \( x = 3 \), \( y = -1 \) or \((3,-1)\).

**Elimination:**
Multiply each side of the first equation by 2 so that the coefficients of \( x \) in the two equations are negatives of each other. The result is the equivalent system
\[
\begin{align*}
-4x + 2y &= -14 \\
4x + 3y &= 9
\end{align*}
\]
We can replace the second equation of this system by the sum of the two equations. The result is the equivalent system
\[
\begin{align*}
-4x + 2y &= -14 \\
5y &= -5
\end{align*}
\]
Now we solve the second equation for \( y \).
\[ 5y = -5 \]
\[ y = \frac{-5}{5} = -1 \]
We back-substitute this value for \( y \) into the original first equation and solve for \( x \).
\[ -2x + y = 7 \]
\[ -2x + (-1) = 7 \]
\[ -2x = 6 \]
\[ x = \frac{-6}{-2} = 3 \]
The solution of the system is \( x = 3 \), \( y = -1 \) or \((3,-1)\).

3.
\[
\begin{align*}
x - y + 2z &= 5 \quad (1) \\
x + 4y - z &= -2 \quad (2) \\
5x + 2y + 3z &= 8 \quad (3)
\end{align*}
\]
We use the method of elimination and begin by eliminating the variable \( y \) from equation (2). Multiply each side of equation (1) by 4 and add the result to equation (2). This result becomes our new equation (2).
\[
\begin{align*}
x - y + 2z &= 5 \\
4x - 4y + 8z &= 20 \\
x + 4y - z &= -2 \\
3x + 4y - z &= -2 \\
7x + 7z &= 18 \quad (2)
\end{align*}
\]
We now eliminate the variable \( y \) from equation (3) by multiplying each side of equation (1) by 2 and adding the result to equation (3). The result becomes our new equation (3).
\[
\begin{align*}
x - y + 2z &= 5 \\
2x - 2y + 4z &= 10 \\
5x + 2y + 3z &= 8 \\
5x + 2y + 3z &= 8 \\
7x + 7z &= 18 \quad (3)
\end{align*}
\]
Our (equivalent) system now looks like
\[
\begin{align*}
x - y + 2z &= 5 \quad (1) \\
7x + 7z &= 18 \quad (2) \\
7x + 7z &= 18 \quad (3)
\end{align*}
\]
Treat equations (2) and (3) as a system of two equations containing two variables, and eliminate the \( x \) variable by multiplying each side of equation (2) by \(-1\) and adding the result to equation (3). The result becomes our new equation (3).
\[
\begin{align*}
x - y + 2z &= 5 \\
-7x - 7z &= -18 \\
7x + 7z &= 18 \\
7x + 7z &= 18 \\
0 &= 0 \quad (3)
\end{align*}
\]
We now have the equivalent system
\[
\begin{align*}
x - y + 2z &= 5 \quad (1) \\
7x + 7z &= 18 \quad (2) \\
0 &= 0 \quad (3)
\end{align*}
\]
This is equivalent to a system of two equations with three variables. Since one of the equations contains three variables and one contains only two variables, the system will be dependent. There are infinitely many solutions.
We solve equation (2) for \( x \) and determine that
\[ x = -z + \frac{18}{7} \]. Substitute this expression into equation (1) to obtain \( y \) in terms of \( z \).
Chapter 8: Systems of Equations and Inequalities

\[
\begin{align*}
x - y + 2z &= 5 \\
\left(-z + \frac{18}{7}\right) - y + 2z &= 5 \\
-\frac{18}{7} - y + 2z &= 5 \\
y + z &= \frac{17}{7} \\
y &= z - \frac{17}{7}
\end{align*}
\]

The solution is \(x = -z + \frac{18}{7}, y = \frac{z}{z} - \frac{17}{7}\).

\(z\) is any real number or \(\{(x, y, z) \mid x = -z + \frac{18}{7}, y = \frac{z}{z} - \frac{17}{7}\}\).

\[\begin{align*}
3x + 2y - 8z &= -3 & (1) \\
-x - \frac{2}{3}y + z &= 1 & (2) \\
6x - 3y + 15z &= 8 & (3)
\end{align*}\]

We start by clearing the fraction in equation (2) by multiplying both sides of the equation by 3.

\[\begin{align*}
3x + 2y - 8z &= -3 & (1) \\
-3x - 2y + 3z &= 3 & (2) \\
6x - 3y + 15z &= 8 & (3)
\end{align*}\]

We use the method of elimination and begin by eliminating the variable \(x\) from equation (2). The coefficients on \(x\) in equations (1) and (2) are negatives of each other so we simply add the two equations together. This result becomes our new equation (2).

\[\begin{align*}
3x + 2y - 8z &= -3 \\
-3x - 2y + 3z &= 3 \\
-5z &= 0 \quad (2)
\end{align*}\]

We now eliminate the variable \(x\) from equation (3) by multiplying each side of equation (1) by \(-2\) and adding the result to equation (3). The result becomes our new equation (3).

\[\begin{align*}
3x + 2y - 8z &= -3 \\
6x - 3y + 15z &= 8 \\
\frac{-7y + 31z = 14}{-7y + 31z = 14} \quad (3)
\end{align*}\]

Our (equivalent) system now looks like

\[\begin{align*}
3x + 2y - 8z &= -3 & (1) \\
-5z &= 0 \quad (2) \\
-7y + 31z &= 14 \quad (3)
\end{align*}\]

We solve equation (2) for \(z\) by dividing both sides of the equation by \(-5\).

\[-5z = 0 \quad \Rightarrow \quad z = 0\]

Back-substitute \(z = 0\) into equation (3) and solve for \(y\).

\[-7y + 31(0) = 14 \quad \Rightarrow \quad -7y = 14 \quad \Rightarrow \quad y = -2\]

Finally, back-substitute \(y = -2\) and \(z = 0\) into equation (1) and solve for \(x\).

\[3x + 2(-2) - 8(0) = -3 \quad \Rightarrow \quad 3x - 4 = -3 \quad \Rightarrow \quad x = \frac{1}{3}\]

The solution of the original system is \(x = \frac{1}{3}, y = -2, z = 0\) or \(\left\{\frac{1}{3}, -2, 0\right\}\).

\[\begin{align*}
4x - 5y + z &= 0 \\
-2x - y + 6 &= -19 \\
x + 5y - 5z &= 10
\end{align*}\]

We first check the equations to make sure that all variable terms are on the left side of the equation and the constants are on the right side. If a variable is missing, we put it in with a coefficient of 0. Our system can be rewritten as

\[\begin{align*}
4x - 5y + z &= 0 \\
-2x - y + 0z &= -19 \\
x + 5y - 5z &= 10
\end{align*}\]

The augmented matrix is

\[
\begin{bmatrix}
4 & -5 & 1 & 0 \\
-2 & -1 & 0 & -25 \\
1 & 5 & -5 & 10
\end{bmatrix}
\]

6. The matrix has three rows and represents a system with three equations. The three columns to the left of the vertical bar indicate that the system has three variables. We can let \(x, y,\) and \(z\) denote these variables. The column to the right of the vertical bar represents the constants on the right side of the equations. The system is

\[\begin{align*}
3x + 2y + 4z &= -6 \\
1x + 0y + 8z &= 2 \quad \text{or} \quad x + 8z = 2 \\
-2x + 1y + 3z &= -11 \quad \Rightarrow \quad -2x + y + 3z = -11
\end{align*}\]
7. \(2A + C = \begin{bmatrix} 1 & -1 \\ 0 & -4 \\ 3 & 2 \end{bmatrix} + \begin{bmatrix} 4 & 6 \\ 2 & -2 \\ 1 & -8 \end{bmatrix} = \begin{bmatrix} 6 & 4 \\ 0 & -8 \\ 6 & 4 \end{bmatrix} \)

8. \(A - 3C = \begin{bmatrix} 1 & -1 \\ 0 & -4 \\ 3 & 2 \end{bmatrix} - \begin{bmatrix} 12 & 18 \\ 3 & -9 \\ -3 & 24 \end{bmatrix} = \begin{bmatrix} -11 & -19 \\ -3 & 5 \\ 6 & -22 \end{bmatrix} \)

9. \(AC\) cannot be computed because the dimensions are mismatched. To multiply two matrices, we need the number of columns in the first matrix to be the same as the number of rows in the second matrix. Matrix \(A\) has 2 columns, but matrix \(C\) has 3 rows. Therefore, the operation cannot be performed.

10. Here we are taking the product of a \(2 \times 3\) matrix and a \(3 \times 2\) matrix. Since the number of columns in the first matrix is the same as the number of rows in the second matrix (3 in both cases), the operation can be performed and will result in a \(2 \times 2\) matrix.

\[
BA = \begin{bmatrix} 1 & -2 & 5 \\ 0 & 3 & 1 \end{bmatrix} \begin{bmatrix} 1 & -1 \\ 0 & -4 \\ 3 & 2 \end{bmatrix} = \begin{bmatrix} 1 \cdot 1 + (-2) \cdot 0 + 5 \cdot 3 & 1 \cdot (-1) + (-2) \cdot 0 + 5 \cdot 2 \\ 0 \cdot 1 + 3 \cdot 0 + 1 \cdot 3 & 0 \cdot (-1) + 3 \cdot 0 + 1 \cdot 2 \end{bmatrix} = \begin{bmatrix} 16 & 17 \\ 3 & -10 \end{bmatrix}
\]

11. We first form the matrix

\[
[A | I_2] = \begin{bmatrix} 3 & 2 & 1 & 0 \\ 5 & 4 & 0 & 1 \end{bmatrix}
\]

Next we use row operations to transform \([A | I_2]\) into reduced row echelon form.

\[
\begin{bmatrix} 3 & 2 & 1 & 0 \\ 5 & 4 & 0 & 1 \end{bmatrix} \rightarrow \begin{bmatrix} 1 \frac{2}{3} & \frac{1}{3} & 0 \\ 0 & \frac{2}{3} & -\frac{5}{3} & -1 \end{bmatrix} \rightarrow \begin{bmatrix} 1 & \frac{2}{3} & \frac{1}{3} & 0 \\ 0 & 1 & -\frac{5}{3} & -\frac{1}{3} \end{bmatrix} \rightarrow \begin{bmatrix} 1 & 0 & \frac{2}{3} & -\frac{1}{3} \\ 0 & 1 & -\frac{5}{3} & -\frac{1}{3} \end{bmatrix}
\]

Thus, \(B^{-1} = \begin{bmatrix} 2 & 1 \\ 2 & 0 \end{bmatrix} \).
Chapter 8: Systems of Equations and Inequalities

13. \[
\begin{align*}
6x + 3y &= 12 \\
2x - y &= -2
\end{align*}
\]
We start by writing the augmented matrix for the system.
\[
\begin{bmatrix}
6 & 3 & | & 12 \\
2 & -1 & | & -2
\end{bmatrix}
\]
Next we use row operations to transform the augmented matrix into row echelon form.
\[
\begin{align*}
\begin{bmatrix}
6 & 3 & | & 12 \\
2 & -1 & | & -2
\end{bmatrix} & \rightarrow \begin{bmatrix}
2 & -1 & | & -2 \\
6 & 3 & | & 12
\end{bmatrix} \quad (R_1 = r_2) \\
& \rightarrow \begin{bmatrix}
1 & -\frac{1}{2} & | & -1 \\
6 & 3 & | & 12
\end{bmatrix} \quad (R_1 = \frac{1}{2}r_1) \\
& \rightarrow \begin{bmatrix}
1 & -\frac{1}{2} & | & -1 \\
0 & 6 & | & 18
\end{bmatrix} \quad (R_2 = -6r_1 + r_2) \\
& \rightarrow \begin{bmatrix}
1 & -\frac{1}{2} & | & -1 \\
0 & 1 & | & 3
\end{bmatrix} \quad (R_2 = \frac{1}{2}r_2 + r_1)
\end{align*}
\]
The solution of the system is \(x = \frac{3}{2}, y = 3\) or \((\frac{3}{2}, 3)\).

14. \[
\begin{align*}
\frac{x}{4} + y &= 7 \\
8x + 2y &= 56
\end{align*}
\]
We start by writing the augmented matrix for the system.
\[
\begin{bmatrix}
1 & \frac{1}{4} & | & 7 \\
8 & 2 & | & 56
\end{bmatrix}
\]
Next we use row operations to transform the augmented matrix into row echelon form.
\[
\begin{align*}
\begin{bmatrix}
1 & \frac{1}{4} & | & 7 \\
8 & 2 & | & 56
\end{bmatrix} & \rightarrow \begin{bmatrix}
1 & \frac{1}{4} & | & 7 \\
0 & 2 & | & 56 - 8\cdot(\frac{1}{4}) - 8\cdot(7)
\end{bmatrix} \\
& \rightarrow \begin{bmatrix}
1 & \frac{1}{4} & | & 7 \\
0 & 1 & | & 0
\end{bmatrix} \\
& \rightarrow \begin{bmatrix}
1 & 0 & | & \frac{3}{4} \\
0 & 1 & | & 0
\end{bmatrix}
\end{align*}
\]
The augmented matrix is now in row echelon form. The last row represents the equation \(z = 0\). Using \(z = 0\) we back-substitute into the equation \(y + 3z = -2\) (from the second row) and obtain \(y + 3(0) = -2\) or \(y = -2\). Using \(y = -2\) and \(z = 0\), we back-substitute into the equation \(x + 2y + 4z = -3\) (from the first row) and obtain \(x + 2(-2) + 4(0) = -3\) or \(x = 1\). The solution is \(x = 1, y = -2, z = 0\) or \((1, -2, 0)\).

15. \[
\begin{align*}
x + 2y + 4z &= -3 \\
2x + 7y + 15z &= -12 \\
4x + 7y + 13z &= -10
\end{align*}
\]
We start by writing the augmented matrix for the system.
\[
\begin{bmatrix}
1 & 2 & 4 & | & -3 \\
2 & 7 & 15 & | & -12 \\
4 & 7 & 13 & | & -10
\end{bmatrix}
\]
Next we use row operations to transform the augmented matrix into row echelon form.
\[
\begin{align*}
\begin{bmatrix}
1 & 2 & 4 & | & -3 \\
2 & 7 & 15 & | & -12 \\
4 & 7 & 13 & | & -10
\end{bmatrix} & \rightarrow \begin{bmatrix}
1 & 2 & 4 & | & -3 \\
0 & 3 & 7 & | & -6 \\
0 & -1 & -3 & | & 2
\end{bmatrix} \quad (R_2 = -2r_1 + r_2) \\
& \rightarrow \begin{bmatrix}
1 & 2 & 4 & | & -3 \\
0 & 1 & 3 & | & -2 \\
0 & 3 & 7 & | & -6
\end{bmatrix} \quad (R_2 = -r_5) \\
& \rightarrow \begin{bmatrix}
1 & 2 & 4 & | & -3 \\
0 & 1 & 3 & | & -2 \\
0 & 0 & -2 & | & 0
\end{bmatrix} \quad (R_3 = -3r_2 + r_3) \\
& \rightarrow \begin{bmatrix}
1 & 2 & 4 & | & -3 \\
0 & 1 & 3 & | & -2 \\
0 & 0 & 1 & | & 0
\end{bmatrix} \quad (R_3 = -\frac{1}{2}r_5)
\end{align*}
\]
The matrix is now in row echelon form. The last row represents the equation \(z = 0\). Using \(z = 0\) we back-substitute into the equation \(y + 3z = -2\) (from the second row) and obtain \(y + 3(0) = -2\) or \(y = -2\). Using \(y = -2\) and \(z = 0\), we back-substitute into the equation \(x + 2y + 4z = -3\) (from the first row) and obtain \(x + 2(-2) + 4(0) = -3\) or \(x = 1\) and we have the system \((1, -2, 0)\) as the solution.
16. \[
\begin{align*}
2x + 2y - 3z &= 5 \\
x - y + 2z &= 8 \\
3x + 5y - 8z &= -2
\end{align*}
\]
We start by writing the augmented matrix for the system.
\[
\begin{bmatrix}
2 & 2 & -3 & 5 \\
1 & -1 & 2 & 8 \\
3 & 5 & -8 & -2
\end{bmatrix}
\]
Next we use row operations to transform the augmented matrix into row echelon form.
\[
\begin{bmatrix}
1 & -1 & 2 & 8 \\
0 & 4 & -7 & -11 \\
0 & 8 & -14 & -26
\end{bmatrix}
\]
\[
\begin{bmatrix}
1 & -1 & 2 & 8 \\
0 & 7 & -11 & -18 \\
0 & 8 & -14 & -26
\end{bmatrix}
\]
\[
\begin{bmatrix}
1 & -1 & 2 & 8 \\
0 & 1 & -\frac{7}{4} & -\frac{11}{4} \\
0 & 0 & -\frac{11}{4} & -\frac{23}{4}
\end{bmatrix}
\]
\[
\begin{bmatrix}
1 & -1 & 2 & 8 \\
0 & 1 & 0 & -1 \\
0 & 0 & 1 & 0
\end{bmatrix}
\]
The last row represents the equation \(0 = -4\) which is a contradiction. Therefore, the system has no solution and is inconsistent.

17. \[
\begin{bmatrix}
2 & 5 \\
3 & 7
\end{bmatrix} = (-2)(7) - (5)(3) = -14 - 15 = -29
\]

18. \[
\begin{bmatrix}
2 & -4 & 6 \\
1 & 4 & 0 \\
-1 & 2 & -4
\end{bmatrix}
\]
\[
2 \begin{bmatrix}
4 & 0 & 1 \\
-4 & 0 & 1 \\
1 & -1 & 2
\end{bmatrix} = 2(4(-4) - 2(0)) + 4[1(-4) - (-1)(0)] + 6[1(2) - (-1)4] = 2(-16) + 4(-4) + 6(6) = -32 - 16 + 36 = -12
\]

19. \[
\begin{align*}
4x + 3y &= -23 \\
3x - 5y &= 19
\end{align*}
\]
The determinant \(D\) of the coefficients of the variables is
\[
D = \begin{vmatrix}
4 & 3 \\
3 & -5
\end{vmatrix} = (4)(-5) - (3)(3) = -20 - 9 = -29
\]
Since \(D \neq 0\), Cramer’s Rule can be applied.
\[
\begin{align*}
D_x &= \frac{1}{3} \begin{vmatrix}
-23 & 3 \\
19 & -5
\end{vmatrix} = (-23)(-5) - (3)(19) = 58 \\
D_y &= \frac{4}{3} \begin{vmatrix}
4 & -23 \\
19 & -5
\end{vmatrix} = (4)(-5) - (-23)(3) = 145
\end{align*}
\]
\[
x = \frac{D_x}{D} = \frac{58}{29} = 2 \\
y = \frac{D_y}{D} = \frac{145}{29} = -5
\]
The solution of the system is \(x = -2, y = -5\) or \((-2, -5)\).

20. \[
\begin{align*}
4x + 3y + 2z &= 15 \\
2x + y - 3z &= -15 \\
5x - 5y + 2z &= 18
\end{align*}
\]
The determinant \(D\) of the coefficients of the variables is
\[
D = \begin{vmatrix}
4 & 3 & 2 \\
2 & 1 & -3 \\
5 & -5 & 2
\end{vmatrix} = (4)(-5) - (3)(18) + (2)(10 - 5) = 4(-15) + 3(-4 + 15) + 2(10 - 5) = -52 + 33 + 10 = -9
\]
Since \(D \neq 0\), Cramer’s Rule can be applied.
\[
\begin{align*}
D_x &= \frac{1}{-9} \begin{vmatrix}
-3 & 2 \\
-3 & 2 \\
18 & 2
\end{vmatrix} = \frac{1}{-9} \begin{vmatrix}
1 & -3 \\
-3 & 2 \\
18 & 2
\end{vmatrix} = \frac{1}{-9} \begin{vmatrix}
-15 & -3 \\
18 & 2
\end{vmatrix} = \frac{1}{-9} \begin{vmatrix}
-15 & 1 \\
18 & -5
\end{vmatrix} = -52 + 33 + 10 = -9
\end{align*}
\]
Chapter 8: Systems of Equations and Inequalities

21. \[
\begin{align*}
3x^2 + y^2 &= 12 \\
y^2 &= 9x
\end{align*}
\]

Substitute $9x$ for $y^2$ into the first equation and solve for $x$:

\[
3x^2 + (9x) = 12 \\
3x^2 + 9x - 12 = 0 \\
x^2 + 3x - 4 = 0 \\
(x - 1)(x + 4) = 0 \\
x = 1 \text{ or } x = -4
\]

Back substitute these values into the second equation to determine $y$:

\[
\begin{align*}
x = 1 : & \quad y^2 = 9(1) = 9 \\
y = \pm 3 & \quad \text{not real}
\end{align*}
\]

\[
\begin{align*}
x = -4 : & \quad y^2 = 9(-4) = -36 \\
y = \pm \sqrt{-36} & \quad \text{not real}
\end{align*}
\]

The solutions of the system are $(1, -3)$ and $(1, 3)$.

22. \[
\begin{align*}
2y^2 - 3x^2 &= 5 \\
y - x &= 1
\end{align*}
\]

Substitute $x + 1$ for $y$ into the first equation and solve for $x$:

\[
\begin{align*}
2(x + 1)^2 - 3x^2 &= 5 \\
2(x^2 + 2x + 1) - 3x^2 &= 5 \\
2x^2 + 4x + 2 - 3x^2 &= 5 \\
-x^2 + 4x - 3 &= 0 \\
x^2 - 4x + 3 &= 0 \\
(x - 1)(x - 3) &= 0 \\
x &= 1 \text{ or } x &= 3
\end{align*}
\]

Back substitute these values into the second equation to determine $y$:

\[
\begin{align*}
x = 1 : & \quad y = 1 + 1 = 2 \\
x = 3 : & \quad y = 3 + 1 = 4
\end{align*}
\]

The solutions of the system are $(1, 2)$ and $(3, 4)$.

23. \[
\begin{align*}
x^2 + y^2 &\leq 100 \\
4x - 3y &\geq 0
\end{align*}
\]

Graph the circle $x^2 + y^2 = 100$. Use a solid curve since the inequality uses $\leq$. Choose a test point not on the circle, such as $(0, 0)$. Since $0^2 + 0^2 \leq 100$ is true, shade the same side of the circle as $(0, 0)$; that is, inside the circle.

Graph the line $4x - 3y = 0$. Use a solid line since the inequality uses $\geq$. Choose a test point not on the line, such as $(0, 1)$. Since $4(0) - 3(1) \geq 0$ is false, shade the opposite side of the line from $(0, 1)$. The overlapping region is the solution.
24. \( \frac{3x+7}{(x+3)^2} \)

The denominator contains the repeated linear factor \( x+3 \). Thus, the partial fraction decomposition takes on the form

\[
\frac{3x+7}{(x+3)^2} = \frac{A}{x+3} + \frac{B}{(x+3)^2}
\]

Clear the fractions by multiplying both sides by \( (x+3)^2 \). The result is the identity

\[
3x+7 = A(x+3) + B
\]

or

\[
3x+7 = Ax + (3A+B)
\]

We equate coefficients of like powers of \( x \) to obtain the system

\[
\begin{align*}
3 &= A \\
7 &= 3A + B
\end{align*}
\]

Therefore, we have \( A = 3 \). Substituting this result into the second equation gives

\[
7 = 3A + B
\]

\[
7 = 3(3) + B
\]

\[
-2 = B
\]

Thus, the partial fraction decomposition is

\[
\frac{3x+7}{(x+3)^2} = \frac{3}{x+3} + \frac{-2}{(x+3)^2}
\]

25. \( \frac{4x^2-3}{x(x^2+3)^2} \)

The denominator contains the linear factor \( x \) and the repeated irreducible quadratic factor \( x^2+3 \). The partial fraction decomposition takes on the form

\[
\frac{4x^2-3}{x(x^2+3)^2} = \frac{A}{x} + \frac{Bx+C}{x^2+3} + \frac{Dx+E}{(x^2+3)^2}
\]

We clear the fractions by multiplying both sides by \( x(x^2+3)^2 \) to obtain the identity

\[
4x^2-3 = A \left(x^2+3\right)^2 + x \left(x^2+3\right) (Bx+C) + x(Dx+E)
\]

Collecting like terms yields

\[
4x^2-3 = (A+B)x^4 + Cx^3 + (6A+3B+D)x^2 + (3C+E)x + (9A)
\]

Equating coefficients, we obtain the system

\[
\begin{align*}
A + B &= 0 \\
C &= 0 \\
6A + 3B + D &= 4 \\
3C + E &= 0 \\
9A &= -3
\end{align*}
\]

From the last equation we get \( A = -\frac{1}{3} \).

Substituting this value into the first equation gives \( B = \frac{1}{3} \). From the second equation, we know \( C = 0 \). Substituting this value into the fourth equation yields \( E = 0 \).

Substituting \( A = -\frac{1}{3} \) and \( B = \frac{1}{3} \) into the third equation gives us

\[
6 \left(-\frac{1}{3}\right) + 3 \left(\frac{1}{3}\right) + D = 4
\]

\[
-2 + 1 + D = 4
\]

\[
D = 5
\]

Therefore, the partial fraction decomposition is

\[
\frac{4x^2-3}{x(x^2+3)^2} = \frac{-\frac{1}{3}}{x} + \frac{\frac{1}{3}x}{x^2+3} + \frac{5x}{(x^2+3)^2}
\]

26. \[
\begin{align*}
x &\geq 0 \\
y &\geq 0 \\
x + 2y &\geq 8 \\
2x - 3y &\geq 2
\end{align*}
\]

The inequalities \( x \geq 0 \) and \( y \geq 0 \) require that the graph be in quadrant I.

\[
x + 2y \geq 8
\]

\[
y \geq -\frac{1}{2} x + 4
\]

Test the point \((0,0)\).

\[
x + 2y \geq 8
\]

\[
0 + 2(0) \geq 8
\]

\[
0 \geq 8
\]

false

The point \((0,0)\) is not a solution. Thus, the graph of the inequality \( x + 2y \geq 8 \) includes the half-plane above the line \( y = -\frac{1}{2} x + 4 \). Because the inequality is non-strict, the line is also part of the graph of the solution.
27. The objective function is \( z = 5x + 8y \). We seek the largest value of \( z \) that can occur if \( x \) and \( y \) are solutions of the system of linear inequalities

\[
\begin{align*}
2x - 3y &\geq 2 \\
y &\leq \frac{2}{3}x - \frac{2}{3}
\end{align*}
\]

Test the point \((0, 0)\).

\( 2x - 3y \geq 2 \\
2(0) - 3(0) \geq 2 \\
0 \geq 2 \text{  false}
\)

The point \((0, 0)\) is not a solution. Thus, the graph of the inequality \(2x - 3y \geq 2\) includes the half-plane below the line \(y = \frac{2}{3}x - \frac{2}{3}\).

Because the inequality is non-strict, the line is also part of the graph of the solution. The overlapping shaded region (that is, the shaded region in the graph below) is the solution to the system of linear inequalities.

The graph is unbounded. The corner points are \((4, 2)\) and \((8, 0)\).

28. Let \( j \) = unit price for flare jeans, \( c \) = unit price for camisoles, and \( t \) = unit price for t-shirts. The given information yields a system of equations with each of the three women yielding an equation.

\[
\begin{align*}
2j + 2c + 4t &= 90 \quad \text{(Megan)} \\
j + 3t &= 42.5 \quad \text{(Paige)} \\
j + 3c + 2t &= 62 \quad \text{(Kara)}
\end{align*}
\]

We can solve this system by using matrices.

\[
\begin{bmatrix}
2 & 2 & 4 & 90 \\
1 & 0 & 3 & 42.5 \\
1 & 3 & 2 & 62
\end{bmatrix}
\]

The last row represents the equation \(6 = 0\).

Substituting this result into \(2j + 2c + 4t = 90\) (from the second row) gives
2.5

\[
y - z = 2.5
\]

\[
y - 6 = 2.5
\]

\[
y = 8.5
\]

Substituting \( z = 6 \) into \( x + 3z = 42.5 \) (from the first row) gives

\[
x + 3(6) = 42.5
\]

\[
x = 24.5
\]

Thus, flare jeans cost $24.50, camisoles cost $8.50, and t-shirts cost $6.00.

Chapter 8 Cumulative Review

1. \( 2x^2 - x = 0 \)

\[
x(2x - 1) = 0
\]

\[
x = 0 \quad \text{or} \quad 2x - 1 = 0
\]

\[
2x = 1
\]

\[
x = \frac{1}{2}
\]

The solution set is \( \left\{ 0, \frac{1}{2} \right\} \).

2. \( \sqrt{3x + 1} = 4 \)

\[
(\sqrt{3x + 1})^2 = 4^2
\]

\[
3x + 1 = 16
\]

\[
3x = 15
\]

\[
x = 5
\]

Check:

\[
\sqrt{3 \cdot 5 + 1} = 4
\]

\[
\sqrt{16} = 4
\]

\[
4 = 4
\]

The solution set is \( \{ 5 \} \).

3. \( 2x^3 - 3x^2 - 8x - 3 = 0 \)

The graph of \( Y_1 = 2x^3 - 3x^2 - 8x - 3 \) appears to have an \( x \)-intercept at \( x = 3 \).

Using synthetic division:

\[
\begin{array}{c|cccc}
3 & 2 & -3 & -8 & -3 \\
 & & 6 & 9 & 3 \\
\hline
 & 2 & 3 & 1 & 0 \\
\end{array}
\]

Therefore, \( 2x^3 - 3x^2 - 8x - 3 = 0 \)

\[
(x - 3)(2x^2 + 3x + 1) = 0
\]

\[
(x - 3)(2x + 1)(x + 1) = 0
\]

\[
x = 3 \quad \text{or} \quad x = -\frac{1}{2} \quad \text{or} \quad x = -1
\]

The solution set is \( \{-1, -\frac{1}{2}, 3\} \).

4. \( 3^x = 9^{x+1} \)

\[
3^x = (3^2)^{x+1}
\]

\[
3^x = 3^{2x+2}
\]

\[
x = 2x + 2
\]

\[
x = -2
\]

The solution set is \( \{-2\} \).

5. \( \log_3 (x - 1) + \log_3 (2x + 1) = 2 \)

\[
\log_3 \left( (x - 1)(2x + 1) \right) = 2
\]

\[
(x - 1)(2x + 1) = 3^2
\]

\[
2x^2 - x - 1 = 9
\]

\[
2x^2 - x - 10 = 0
\]

\[
(2x - 5)(x + 2) = 0
\]

\[
x = \frac{5}{2} \quad \text{or} \quad x = -2
\]

Since \( x = -2 \) makes the original logarithms undefined, the solution set is \( \left\{ \frac{5}{2} \right\} \).

6. \( 3^x = e \)

\[
\ln(3^x) = \ln e
\]

\[
x \ln 3 = 1
\]

\[
x = \frac{1}{\ln 3} \approx 0.910
\]

The solution set is \( \left\{ \frac{1}{\ln 3} \approx 0.910 \right\} \).

7. \( g(x) = \frac{2x^3}{x^4 + 1} \)

\[
g(-x) = \frac{2(-x)^3}{(-x)^4 + 1} = -\frac{2x^3}{x^4 + 1} = -g(x)
\]

Thus, \( g \) is an odd function and its graph is symmetric with respect to the origin.
Chapter 8: Systems of Equations and Inequalities

8. \[ \begin{align*} x^2 + y^2 - 2x + 4y - 11 &= 0 \\ x^2 - 2x + y^2 + 4y &= 11 \\ (x^2 - 2x + 1) + (y^2 + 4y + 4) &= 11 + 1 + 4 \\ (x - 1)^2 + (y + 2)^2 &= 16 \\ \text{Center: } (1, -2); \text{ Radius: } 4 \end{align*} \]

9. \[ f(x) = 3^{x-2} + 1 \]
Using the graph of \( y = 3^x \), shift the graph horizontally 2 units to the right, then shift the graph vertically upward 1 unit.

10. \[ f(x) = \frac{5}{x+2} \]
\[ \begin{align*} y &= \frac{5}{x+2} \\ x &= \frac{5}{y+2} & \text{Inverse} \\ x(y + 2) &= 5 \\ xy + 2x &= 5 \\ xy &= 5 - 2x \\ y &= \frac{5 - 2x}{x} = \frac{5}{x} - 2 \\ \text{Thus, } f^{-1}(x) &= \frac{5}{x} - 2 \\ \text{Domain of } f &= \{ x \mid x \neq -2 \} \\ \text{Range of } f &= \{ y \mid y \neq 0 \} \\ \text{Domain of } f^{-1} &= \{ x \mid x \neq 0 \} \\ \text{Range of } f^{-1} &= \{ y \mid y \neq -2 \}. \end{align*} \]

11. a. \[ y = 3x + 6 \]
The graph is a line.
\[ x\text{-intercept: } 0 = 3x + 6 \]
\[ y = 3(0) + 6 \]
\[ 3x = -6 \]
\[ x = -2 \]
\[ y = 6 \]

b. \[ x^2 + y^2 = 4 \]
The graph is a circle with center (0, 0) and radius 2.

c. \[ y = x^3 \]
d. $y = \frac{1}{x}$

![Graph of $y = \frac{1}{x}$](image1)

e. $y = \sqrt{x}$

![Graph of $y = \sqrt{x}$](image2)

f. $y = e^x$

![Graph of $y = e^x$](image3)

g. $y = \ln x$

![Graph of $y = \ln x$](image4)

h. $2x^2 + 5y^2 = 1$

The graph is an ellipse.

$$\frac{x^2}{\frac{1}{2}} + \frac{y^2}{\frac{1}{5}} = 1$$

$$\left(\frac{x}{\frac{\sqrt{2}}{2}}\right)^2 + \left(\frac{y}{\frac{\sqrt{5}}{5}}\right)^2 = 1$$

![Graph of $2x^2 + 5y^2 = 1$](image5)

i. $x^2 - 3y^2 = 1$

The graph is a hyperbola

$$\frac{x^2}{\frac{1}{3}} - \frac{y^2}{\frac{1}{3}} = 1$$

$$\left(\frac{x}{\frac{1}{\sqrt{3}}}\right)^2 - \left(\frac{y}{\frac{1}{\sqrt{3}}}\right)^2 = 1$$

![Graph of $x^2 - 3y^2 = 1$](image6)
Chapter 8: Systems of Equations and Inequalities

j. \[x^2 - 2x - 4y + 1 = 0\]
   \[x^2 - 2x + 1 = 4y\]
   \[4y = (x - 1)^2\]
   \[y = \frac{1}{4}(x - 1)^2\]

\[f(x) = x^3 - 3x + 5\]

a. Let \(Y_i = x^3 - 3x + 5\).

The zero of \(f\) is approximately \(-2.28\).

b. \(f\) has a local maximum of 7 at \(x = -1\) and a local minimum of 3 at \(x = 1\).

c. \(f\) is increasing on the intervals \((-\infty, -1)\) and \((1, \infty)\).

Chapter 8 Projects

Project I

1. \[
\begin{bmatrix}
0.80 & 0.18 & 0.02 \\
0.40 & 0.50 & 0.10 \\
0.20 & 0.60 & 0.20 \\
\end{bmatrix}
\]
2. \[
\begin{bmatrix}
0.80 & 0.18 + 0.02 = 1.00 \\
0.40 + 0.50 + 0.10 = 1.00 \\
0.20 + 0.60 + 0.20 = 1.00 \\
\end{bmatrix}
\]
   The sum of each row is 1 (or 100%). These represent the three possibilities of educational achievement for a parent of a child, unless someone does not attend school at all. Since these are rounded percents, chances are the other possibilities are negligible.

4. \[
P^{(2)} = \begin{bmatrix}
0.80 & 0.18 & 0.02 \\
0.40 & 0.50 & 0.10 \\
0.20 & 0.60 & 0.20 \\
\end{bmatrix}
= \begin{bmatrix}
0.716 & 0.246 & 0.038 \\
0.54 & 0.382 & 0.078 \\
0.44 & 0.456 & 0.104 \\
\end{bmatrix}
\]
   Grandchild of a college graduate is a college graduate: entry (1, 1): 0.716. The probability is 71.6%.

5. Grandchild of a high school graduate finishes college: entry (2,1): 0.54. The probability is 54%.

6. Grandchildren \(\rightarrow k = 2\).
   \[
v^{(2)} = v^{(0)}P^{2}
= \begin{bmatrix}
0.716 & 0.246 & 0.038 \\
0.54 & 0.382 & 0.078 \\
0.44 & 0.456 & 0.104 \\
\end{bmatrix}
= \begin{bmatrix}
0.573952 & 0.35528 & 0.070768 \\
\end{bmatrix}
\]
   College: \(\approx 57\%\)
   High School: \(\approx 36\%\)
   Elementary: \(\approx 7\%\)

7. The matrix totally stops changing at
   \[
